\textit{Dedicated to the memory of John McCarthy}

\textbf{13 February 2012}
The report gives a defining description of the programming language Scheme. Scheme is a statically scoped and properly tail recursive dialect of the Lisp programming language invented by Guy Lewis Steele Jr. and Gerald Jay Sussman. It was designed to have an exceptionally clear and simple semantics and few different ways to form expressions. A wide variety of programming paradigms, including imperative, functional, and object-oriented styles, find convenient expression in Scheme.

The introduction offers a brief history of the language and of the report.

The first three chapters present the fundamental ideas of the language and describe the notational conventions used for describing the language and for writing programs in the language.

Chapters 4 and 5 describe the syntax and semantics of expressions, definitions, programs, and libraries.

Chapter 6 describes Scheme’s built-in procedures, which include all of the language’s data manipulation and input/output primitives.

Chapter 7 provides a formal syntax for Scheme written in extended BNF, along with a formal denotational semantics. An example of the use of the language follows the formal syntax and semantics.

Appendix A provides a list of the standard libraries and the identifiers that they export.

Appendix B provides a list of optional but standardized implementation feature names.

The report concludes with a list of references and an alphabetic index.

*** DRAFT***

February 14, 2012
INTRODUCTION

Programming languages should be designed not by piling feature on top of feature, but by removing the weaknesses and restrictions that make additional features appear necessary. Scheme demonstrates that a very small number of rules for forming expressions, with no restrictions on how they are composed, suffice to form a practical and efficient programming language that is flexible enough to support most of the major programming paradigms in use today.

Scheme was one of the first programming languages to incorporate first class procedures as in the lambda calculus, thereby proving the usefulness of static scope rules and block structure in a dynamically typed language. Scheme was the first major dialect of Lisp to distinguish procedures from lambda expressions and symbols, to use a single lexical environment for all variables, and to evaluate the operator position of a procedure call in the same way as an operand position. By relying entirely on procedure calls to express iteration, Scheme emphasized the fact that tail-recursive procedure calls are essentially GOTO’s that pass arguments, thus allowing a programming style that is both coherent and efficient. Scheme was the first widely used programming language to embrace first class escape procedures, from which all previously known sequential control structures can be synthesized. A subsequent version of Scheme introduced the concept of exact and inexact numbers, an extension of Common Lisp’s generic arithmetic. More recently, Scheme became the first programming language to support hygienic macros, which permit the syntax of a block-structured language to be extended in a consistent and reliable manner.

Background

The first description of Scheme was written in 1975 [36]. A revised report [33] appeared in 1978, which described the evolution of the language as its MIT implementation was upgraded to support an innovative compiler [34]. Three distinct projects began in 1981 and 1982 to use variants of Scheme for courses at MIT, Yale, and Indiana University [29, 25, 16]. An introductory computer science textbook using Scheme was published in 1984 [3].

As Scheme became more widespread, local dialects began to diverge until students and researchers occasionally found it difficult to understand code written at other sites. Fifteen representatives of the major implementations of Scheme therefore met in October 1984 to work toward a better and more widely accepted standard for Scheme. Their report, the RRRS [3], was published at MIT and Indiana University in the summer of 1985. Further revision took place in the spring of 1986, resulting in the R^3RS [31]. Work in the spring of 1988 resulted in R^4RS [10], which became the basis for the IEEE Standard for the Scheme Programming Language in 1991 [20]. In 1998, several additions to the IEEE standard, including high-level hygienic macros, multiple return values and eval, were finalized as the R^6RS [2].

In the fall of 2006, work began on a more ambitious standard, including many new improvements and stricter requirements made in the interest of improved portability. The resulting standard, the R^8RS, was completed in August 2007 [1], and was organized as a core language and set of mandatory standard libraries. The size and goals of the R^6RS, however, were controversial, and adoption of the new standard was not as widespread as had been hoped.

In consequence, the Scheme Steering Committee decided in August 2009 to divide the standard into two separate but compatible languages — a “small” language, suitable for educators, researchers and embedded languages, focused on R^3RS compatibility, and a “large” language focused on the practical needs of mainstream software development which would evolve to become a replacement for R^6RS. The present report describes the “small” language of that effort.

We intend this report to belong to the entire Scheme community, and so we grant permission to copy it in whole or in part without fee. In particular, we encourage implementors of Scheme to use this report as a starting point for manuals and other documentation, modifying it as necessary.

Acknowledgements

We would like to thank the members of the Steering Committee, William Clinger, Marc Feeley, Chris Hanson, Jonathan Rees, and Olin Shivers, for their support and guidance. We’d like to thank the following people for their help: Per Bothner, Taylor Campbell, Ray Dillinger, Brian Harvey, Shiro Kawai, Jonathan Kraut, Thomas Lord, Vincent Manis, Jeronimo Pellegrini, Jussi Piitulainen, Alex Queiroz, Jim Rees, Jay Reynolds Freeman, Malcolm Tredinnick, Denis Washington, Andy Wingo, and Andre van Tonder.

In addition we would like to thank all the past editors, and the people who helped them in turn: Hal Abelson, Norman Adams, David Bartley, Alan Bawden, Michael Blair, Gary Brooks, George Carrette, Andy Cromarty, Pavel Curtis, Jeff Dalton, Olivier Danvy, Ken Dickey, Bruce Duba, Robert Findler, Andy Freeman, Richard Gabriel, Yekta G"ursel, Ken Haase, Robert Halstead, Robert Hieb, Paul Hudak, Morry Katz, Eugene Kohlbecker, Chris Lindblad, Jacob Matthews, Mark Meyer, Jim Miller, Don Oxley, Jim Philbin, Kent Pitman, John Ramsdell, Guillermo Rozas, Mike Shafl, Jonathan Shapiro, Guy Steele, Julie Sussman, Perry Wagle, Mitchel Wand, Daniel Weise, Henry Wu, and...
Ozan Yigit. We thank Carol Fessenden, Daniel Friedman, and Christopher Haynes for permission to use text from the Scheme 311 version 4 reference manual. We thank Texas Instruments, Inc. for permission to use text from the *TI Scheme Language Reference Manual* [38]. We gladly acknowledge the influence of manuals for MIT Scheme [25], T [30], Scheme 84 [17], Common Lisp [35], and Algol 60 [26].
1. Overview of Scheme

1.1. Semantics

This section gives an overview of Scheme’s semantics. A detailed informal semantics is the subject of chapters 3 through 6. For reference purposes, section 7.2 provides a formal semantics of Scheme.

Scheme is a statically scoped programming language. Each use of a variable is associated with a lexically apparent binding of that variable.

Scheme is a dynamically typed language. Types are associated with values (also called objects) rather than with variables. Statically typed languages, by contrast, associate types with variables and expressions as well as with values.

All objects created in the course of a Scheme computation, including procedures and continuations, have unlimited extent. No Scheme object is ever destroyed. The reason that implementations of Scheme do not (usually!) run out of storage is that they are permitted to reclaim the storage occupied by an object if they can prove that the object cannot possibly matter to any future computation.

Implementations of Scheme are required to be properly tail-recursive. This allows the execution of an iterative computation in constant space, even if the iterative computation is described by a syntactically recursive procedure. Thus with a properly tail-recursive implementation, iteration can be expressed using the ordinary procedure-call mechanics, so that special iteration constructs are useful only as syntactic sugar. See section 3.5.

Scheme procedures are objects in their own right. Procedures can be created dynamically, stored in data structures, returned as results of procedures, and so on.

One distinguishing feature of Scheme is that continuations, which in most other languages only operate behind the scenes, also have “first-class” status. Continuations are useful for implementing a wide variety of advanced control constructs, including non-local exits, backtracking, and coroutines. See section 6.10.

Arguments to Scheme procedures are always passed by value, which means that the actual argument expressions are evaluated before the procedure gains control, regardless of whether the procedure needs the result of the evaluation.

Scheme’s model of arithmetic is designed to remain as independent as possible of the particular ways in which numbers are represented within a computer. In Scheme, every integer is a rational number, every rational is a real, and every real is a complex number. Thus the distinction between integer and real arithmetic, so important to many programming languages, does not appear in Scheme. In its place is a distinction between exact arithmetic, which corresponds to the mathematical ideal, and inexact arithmetic on approximations. Exact arithmetic is not limited to integers.

1.2. Syntax

Scheme, like most dialects of Lisp, employs a fully parenthesized prefix notation for programs and other data; the grammar of Scheme generates a sublanguage of the language used for data. An important consequence of this simple, uniform representation is that Scheme programs and data can easily be treated uniformly by other Scheme programs. For example, the eval procedure evaluates a Scheme program expressed as data.

The read procedure performs syntactic as well as lexical decomposition of the data it reads. The read procedure parses its input as data (section 7.1.2), not as program.

The formal syntax of Scheme is described in section 7.1.

1.3. Notation and terminology

1.3.1. Base and optional features

Every identifier defined in this report appears in one of several libraries. Identifiers defined in the base library are not marked specially in the body of the report. A summary of all the standard libraries and the features they provide is given in Appendix A.

Implementations must provide the base library and all the identifiers exported from it. Implementations are free to provide or omit the other libraries given in this report, but each library must either be provided in its entirety, exporting no additional identifiers, or else omitted altogether.

Implementations may provide other libraries not described in this report. Implementations may also extend the function of any identifier in this report, provided the extensions are not in conflict with the language reported here. In particular, implementations must support portable code by providing a mode of operation in which the lexical syntax does not conflict with the lexical syntax described in this report.

1.3.2. Error situations and unspecified behavior

When speaking of an error situation, this report uses the phrase “an error is signalled” to indicate that implementations must detect and report the error. An error is signalled by raising a non-continuable exception, as if by the procedure raise as described in section 6.11. The object raised
is implementation-dependent and need not be a newly allocated object every time. In addition to errors signalled by situations described in this report, programmers may signal their own errors and handle signalled errors.

If such wording does not appear in the discussion of an error, then implementations are not required to detect or report the error, though they are encouraged to do so. Such a situation is sometimes, but not always, referred to with the phrase “an error.” For example, it is an error for a procedure to be passed an argument of a type that the procedure is not explicitly specified to handle, even though such domain errors are seldom mentioned in this report. Implementations may extend a procedure’s domain of definition to include such arguments.

This report uses the phrase “may report a violation of an implementation restriction” to indicate circumstances under which an implementation is permitted to report that it is unable to continue execution of a correct program because of some restriction imposed by the implementation. Implementation restrictions are discouraged, but implementations are encouraged to report violations of implementation restrictions.

For example, an implementation may report a violation of an implementation restriction if it does not have enough storage to run a program, or if an arithmetic operation would produce an exact number that is too large for the implementation to represent.

If the value of an expression is said to be “unspecified,” then the expression must evaluate to some object without signalling an error, but the value depends on the implementation; this report explicitly does not say what value is returned.

Finally, the words and phrases “must,” “must not,” “shall,” “shall not,” “should,” “should not,” “may,” “required,” “recommended,” and “optional,” although not capitalized in this report, are to be interpreted as described in RFC 2119 [6]. In particular, “must” and “must not” are used only when absolute restrictions are placed on implementations.

1.3.3. Entry format

Chapters 4 and 6 are organized into entries. Each entry describes one language feature or a group of related features, where a feature is either a syntactic construct or a procedure. An entry begins with one or more header lines of the form

```plaintext
template category
```

for identifiers in the base library, or

```plaintext
template library category
```

where `library` is the short name of a library as defined in Appendix A.

If `category` is “syntax,” the entry describes an expression type, and the template gives the syntax of the expression type. Components of expressions are designated by syntactic variables, which are written using angle brackets, for example, `<expression>`, `<variable>`. Syntactic variables are intended to denote segments of program text; for example, `<expression>` stands for any string of characters which is a syntactically valid expression. The notation

```plaintext
<thing1> ...
```

indicates zero or more occurrences of a `<thing>`, and

```plaintext
<thing1> <thing2> ...
```

indicates one or more occurrences of a `<thing>`. If `category` is “auxiliary syntax,” then the entry describes a syntax binding that occurs only as part of specific surrounding expressions. Any use as an independent syntactic construct or identifier is an error.

If `category` is “procedure,” then the entry describes a procedure, and the header line gives a template for a call to the procedure. Argument names in the template are italicized. Thus the header line

```plaintext
(vector-ref vector k)
```

indicates that the procedure bound to the `vector-ref` variable takes two arguments, a vector `vector` and an exact non-negative integer `k` (see below). The header lines

```plaintext
(make-vector k)
(make-vector k fill)
```

indicate that the `make-vector` procedure must be defined to take either one or two arguments.

It is an error for an operation to be presented with an argument that it is not specified to handle. For succinctness, we follow the convention that if an argument name is also the name of a type listed in section 3.2, then it is an error if that argument is not of the named type. For example, the header line for `vector-ref` given above dictates that the first argument to `vector-ref` is a vector. The following
naming conventions also imply type restrictions:

- **obj**: any object
- **list, list₁, ..., listₖ**: list (see section 6.4)
- **z, z₁, ..., zₖ**: complex number
- **x, x₁, ..., xₖ**: real number
- **y, y₁, ..., yₖ**: real number
- **q, q₁, ..., qₖ**: rational number
- **n, n₁, ..., nₖ**: integer
- **k₁, ..., kₖ**: exact non-negative integer
- **string**: string
- **pair**: pair
- **alist**: association list (list of pairs)
- **symbol**: symbol
- **letter**: alphabetic character
- **byte**: exact non-negative integer < 256
- **bytevector**: bytevector
- **thunk**: zero-argument procedure
- **port**: port

### 2. Lexical conventions

This section gives an informal account of some of the lexical conventions used in writing Scheme programs. For a formal syntax of Scheme, see section 7.1.

#### 2.1. Identifiers

An identifier is any sequence of letters, digits, and “extended identifier characters” provided that it does not have a prefix which is a valid number. However, the . token (a single period) used in the list syntax is not an identifier.

All implementations of Scheme must support the following extended identifier characters:

```
! $ % & * + - . / : < = > ? @ ^ _ ~
```

In addition, any character supported by an implementation can be used within an identifier when specified using an ⟨inline hex escape⟩. For example, the identifier H\x65;1lo is the same as the identifier Hello, and in an implementation that supports the appropriate Unicode character the identifier \x3BB; is the same as the identifier λ.

As a convenience, identifiers may also be written as a sequence of zero or more characters enclosed within vertical bars (|), analogous to string literals. Any character, including whitespace characters, but excluding the backslash and vertical bar characters, may appear verbatim in such an identifier. It is also possible to include the backslash and vertical bar characters, as well as any other character, in the identifier with an ⟨inline hex escape⟩. Thus the identifier |foo bar| is the same as the identifier foo\x20;bar. Note that || is a valid identifier that is not equal to any other identifier.

Here are some examples of identifiers:

```
lambda q
list->vector +soup+
+ V17a
<=? a34kTMNs
->string ...
|two words| two\x20;words
the-word-recursion-has-many-meanings
```

See section 7.1.1 for the formal syntax of identifiers.

Identifiers have two uses within Scheme programs:

- Any identifier may be used as a variable or as a syntactic keyword (see sections 3.1 and 4.3).
- When an identifier appears as a literal or within a literal (see section 4.1.2), it is being used to denote a symbol (see section 6.5).
In contrast with earlier revisions of the report [2], the syntax distinguishes between upper and lower case in identifiers and in characters specified using their names. However, it does not distinguish between upper and lower case in numbers, nor in (inline hex escapes) used in the syntax of identifiers, characters, or strings. None of the identifiers defined in this report contain upper-case characters, even when they may appear to do so as a result of the English-language convention of capitalizing the word at the beginning of a sentence.

The following directives give explicit control over case folding.

```scheme
#!fold-case
#!no-fold-case
```

These directives may appear anywhere comments are permitted (see section 2.2) and are treated as comments, except that they affect the reading of subsequent data. The `#!fold-case` directive causes the read procedure to case-fold (as if by `string-foldcase`; see section 6.1) each identifier and character name subsequently read from the same port. (It has no effect on character literals.) The `#!no-fold-case` directive causes the read procedure to return to the default, non-folding behavior.

2.2. Whitespace and comments

Whitespace characters include the space and newline characters. (Implementations may provide additional whitespace characters such as tab or page break.) Whitespace is used for improved readability and as necessary to separate tokens from each other, a token being an indivisible lexical unit such as an identifier or number, but is otherwise insignificant. Whitespace can occur between any two tokens, but not within a token. Whitespace occurring inside a string or inside a symbol delimited by vertical bars is significant.

The lexical syntax includes several comment forms. Comments are treated exactly like whitespace.

A semicolon (;) indicates the start of a line comment. The comment continues to the end of the line on which the semicolon appears. Comments are invisible to Scheme, but the end of the line is visible as whitespace. This prevents a comment from appearing in the middle of an identifier or number.

Another way to indicate a comment is to prefix a ⟨datum⟩ (cf. section 7.1.2 with #; and optional ⟨whitespace⟩. The comment consists of the comment prefix #; the space, and the ⟨datum⟩ together. This notation is useful for “commenting out” sections of code.

Block comments are indicated with properly nested #| and #| pairs.

```scheme
| The FACT procedure computes the factorial of a non-negative integer. |
| (define fact |
| (lambda (n) |
| (if (= n 0) |
| #; (= n 1) |
| 1 ;Base case: return 1 |
| (* n (fact (- n 1)))))) |
```

2.3. Other notations

For a description of the notations used for numbers, see section 6.2.

. + - These are used in numbers, and may also occur anywhere in an identifier. A delimited plus or minus sign by itself is also an identifier. A delimited period (not occurring within a number or identifier) is used in the notation for pairs (section 6.4), and to indicate a rest-parameter in a formal parameter list (section 4.1.4). Note that a sequence of two or more periods is an identifier.

() Parentheses are used for grouping and to notate lists (section 6.4).

' The single quote character is used to indicate literal data (section 4.1.2).

` The backquote character is used to indicate partly constant data (section 4.2.8).

,, The character comma and the sequence comma at-sign are used in conjunction with backquote (section 4.2.8).

" The double quote character is used to delimit strings (section 6.7).

\ Backslash is used in the syntax for character constants (section 6.6) and as an escape character within string constants (section 6.7) and identifiers (section 7.1.1).

[ ] { } Left and right square brackets and curly braces are reserved for possible future extensions to the language.

# Sharp sign is used for a variety of purposes depending on the character that immediately follows it:

#t #f These are the boolean constants (section 6.3), along with the alternatives #true and #false.

#\ This introduces a character constant (section 6.6).

#( This introduces a vector constant (section 6.8). Vector constants are terminated by ).
quasiquote

(section 4.2.8) to contain them.

references except in literals. In particular, it is an error for

labelled by

# It is an error for a

point. The value stored in the location to which a variable

environment a program is known as the

bound to that syntax. An identifier that names a location

type of syntax is called a

identifier names either a type of syntax or a location

point. The value stored in the location to which a variable

is bound is called the variable’s value. By abuse of termin-

ology, the variable is sometimes said to name the value or
to be bound to the value. This is not quite accurate, but

confusion rarely results from this practice.

Certain expression types are used to create new kinds of
syntax and to bind syntactic keywords to those new syn-
taxes, while other expression types create new locations
and bind variables to those locations. These expression
types are called binding constructs. Those that bind syn-
tactic keywords are listed in section 4.3. The most funda-
mental of the variable binding constructs is the lambda
expression, because all other variable binding constructs
can be explained in terms of lambda expressions. The
other variable binding constructs are let, let*, letrec,
letrec*, let-values, let*values, and do expressions
(see sections 4.1.4, 4.2.2, and 4.2.4).

Scheme is a language with block structure. To each place
where an identifier is bound in a program there correspon-
ds a region of the program text within which the binding is
visible. The region is determined by the particular bind-

ing construct that establishes the binding; if the binding is
established by a lambda expression, for example, then its
region is the entire lambda expression. Every mention of
an identifier refers to the binding of the identifier that es-

lished the innermost of the regions containing the use.
If there is no binding of the identifier whose region con-
tains the use, then the use refers to the binding for the
variable in the top level environment, if any (chapters 4
and 5); if there is no binding for the identifier, it is said to
be unbound.

3. Disjointness of types

No object satisfies more than one of the following predi-
cates:

| boolean? | pair? |
| symbol? | number? |
| char? | string? |
| vector? | bytevector? |
| port? | procedure? |
| null? |

These predicates define the types boolean, pair, symbol,
number, char (or character), string, vector, bytevector, port,
procedure, and the empty list object.

Although there is a separate boolean type, any Scheme
value can be used as a boolean value for the purpose of
a conditional test. As explained in section 6.3 all values
count as true in such a test except for #f. This report uses
the word “true” to refer to any Scheme value except #f,
and the word “false” to refer to #f.
3.3. External representations

An important concept in Scheme (and Lisp) is that of the external representation of an object as a sequence of characters. For example, an external representation of the integer 28 is the sequence of characters “28,” and an external representation of a list consisting of the integers 8 and 13 is the sequence of characters “(8 13).”

The external representation of an object is not necessarily unique. The integer 28 also has representations “#e28.0000” and “#x1c,” and the list in the previous paragraph also has the representations “(08 13)” and “(8 . (13 . ())).” (section 6.4).

Many objects have standard external representations, but some, such as procedures, do not have standard representations (although particular implementations may define representations for them).

An external representation can be written in a program to obtain the corresponding object (see quote, section 4.1.2).

External representations can also be used for input and output. The procedure read (section 6.13.2) parses external representations, and the procedure write (section 6.13.3) generates them. Together, they provide an elegant and powerful input/output facility.

Note that the sequence of characters “(+ 2 6)” is not an external representation of the integer 8, even though it is an expression evaluating to the integer 8; rather, it is an external representation of a three-element list, the elements of which are the symbol + and the integers 2 and 6. Scheme’s syntax has the property that any sequence of characters that is an expression is also the external representation of some object. This can lead to confusion, since it is not always obvious out of context whether a given sequence of characters is intended to denote data or program, but it is also a source of power, since it facilitates writing programs such as interpreters and compilers that treat programs as data (or vice versa).

The syntax of external representations of various kinds of objects accompanies the description of the primitives for manipulating the objects in the appropriate sections of chapter 6.

An object fetched from a location, by a variable reference or by a procedure such as car, vector-ref, or string-ref, is equivalent in the sense of eqv? (section 6.1) to the object last stored in the location before the fetch.

Every location is marked to show whether it is in use. No variable or object ever refers to a location that is not in use. Whenever this report speaks of storage being allocated for a variable or object, what is meant is that an appropriate number of locations are chosen from the set of locations that are not in use, and the chosen locations are marked to indicate that they are now in use before the variable or object is made to denote them.

Every object that denotes locations is either mutable or immutable. Literal constants, the strings returned by symbol->string, and possibly the environment returned by scheme-report-environment are immutable objects. All objects created by the other procedures listed in this report are mutable. It is an error to attempt to store a new value into a location that is denoted by an immutable object.

These locations should be understood as conceptual, not physical. Hence, they do not necessarily correspond to memory addresses, and even if they do, the memory address may not be constant.

Rationale: In many systems it is desirable for constants (i.e. the values of literal expressions) to reside in read-only memory. Making it an error to alter constants permits this implementation strategy, while not requiring other systems to distinguish between mutable and immutable objects.

3.5. Proper tail recursion

Implementations of Scheme are required to be properly tail-recursive. Procedure calls that occur in certain syntactic contexts defined below are tail calls. A Scheme implementation is properly tail-recursive if it supports an unbounded number of active tail calls. A call is active if the called procedure might still return. Note that this includes calls that might be returned from either by the current continuation or by continuations captured earlier by call-with-current-continuation that are later invoked.

In the absence of captured continuations, calls could return at most once and the active calls would be those that had not yet returned. A formal definition of proper tail recursion can be found in [12].

Rationale:

Intuitively, no space is needed for an active tail call because the continuation that is used in the tail call has the same semantics as the continuation passed to the procedure containing the call. Although an improper implementation might use a new continuation in the call, a return to this new continuation would be followed immediately by a return to the continuation passed
to the procedure. A properly tail-recursive implementation returns to that continuation directly.

Proper tail recursion was one of the central ideas in Steele and Sussman’s original version of Scheme. Their first Scheme interpreter implemented both functions and actors. Control flow was expressed using actors, which differed from functions in that they passed their results on to another actor instead of returning to a caller. In the terminology of this section, each actor finished with a tail call to another actor.

Steele and Sussman later observed that in their interpreter the code for dealing with actors was identical to that for functions and thus there was no need to include both in the language.

A tail call is a procedure call that occurs in a tail context. Tail contexts are defined inductively. Note that a tail context is always determined with respect to a particular lambda expression.

- The last expression within the body of a lambda expression, shown as ⟨tail expression⟩ below, occurs in a tail context. The same is true of all the bodies of case-lambda expressions.

\[
\text{(lambda} \ (\text{formals}) \ (\text{definition})* \ (\text{expression})* \ (\text{tail expression}))
\]

- If one of the following expressions is in a tail context, then the subexpressions shown as ⟨tail expression⟩ are in a tail context. These were derived from rules in the grammar given in chapter 7 by replacing some occurrences of ⟨body⟩ with ⟨tail body⟩, some occurrences of ⟨expression⟩ with ⟨tail expression⟩, and some occurrences of ⟨sequence⟩ with ⟨tail sequence⟩. Only those rules that contain tail contexts are shown here.

\[
\text{(if} \ (\text{expression}) \ (\text{tail expression}) \ (\text{tail expression})) \\
(\text{if} \ (\text{expression}) \ (\text{tail expression})) \\
(\text{cond} \ (\text{cond clause})^+) \\
(\text{cond} \ (\text{cond clause})* \ (\text{else} \ (\text{tail sequence}))) \\
(\text{case} \ (\text{expression}) \\
(\text{case clause})^+) \\
(\text{case} \ (\text{expression}) \\
(\text{case clause})* \\
(\text{else} \ (\text{tail sequence}))) \\
(\text{and} \ (\text{expression})* \ (\text{tail expression})) \\
(\text{or} \ (\text{expression})* \ (\text{tail expression})) \\
(\text{when} \ (\text{test}) \ (\text{tail sequence})) \\
(\text{unless} \ (\text{test}) \ (\text{tail sequence})) \\
(\text{let} \ ((\text{binding spec})* \ (\text{tail body})) \\
(\text{let} \ (\text{variable}) \ ((\text{binding spec})* \ (\text{tail body}))
\]

- If a cond or case expression is in a tail context, and has a clause of the form ((expression\textsubscript{1}) \Rightarrow \langle expression\textsubscript{2}⟩) then the (implied) call to the procedure that results from the evaluation of ⟨expression\textsubscript{2}⟩ is in a tail context. ⟨expression\textsubscript{2}⟩ itself is not in a tail context.

- Note that (cond clause)s appear in guard expressions as well as cond expressions.

Certain procedures defined in this report are also required to perform tail calls. The first argument passed to apply and to call-with-current-continuation, and the second argument passed to call-with-values, must be called via a tail call. Similarly, eval must evaluate its first argument as if it were in tail position within the eval procedure.

In the following example the only tail call is the call to f. None of the calls to g or h are tail calls. The reference to x is in a tail context, but it is not a call and thus is not a tail call.

\[
\text{(lambda} () \\
(\text{if} \ (g) \\
(\text{let} \ ((x \ (h))) \\
x) \\
(\text{and} \ (g) \ (f)))))
\]

Note: Implementations are allowed, but not required, to recognize that some non-tail calls, such as the call to h above, can be evaluated as though they were tail calls. In the example above, the let expression could be compiled as a tail call to h.
possibility of returning an unexpected number of values can be ignored, because in that case the effect of the let is explicitly unspecified and implementation-dependent.)

4. Expressions

Expression types are categorized as primitive or derived. Primitive expression types include variables and procedure calls. Derived expression types are not semantically primitive, but can instead be defined as macros. Suitable definitions of some of the derived expressions are given in section 7.3.

The procedures force, eager, and make-parameter are also described in this chapter because they are intimately associated with the delay, lazy, and parameterize expression types.

4.1. Primitive expression types

4.1.1. Variable references

(variable) syntax

An expression consisting of a variable (section 3.1) is a variable reference. The value of the variable reference is the value stored in the location to which the variable is bound. It is an error to reference an unbound variable.

(define x 28)
x ⇒ 28

4.1.2. Literal expressions

(quote ⟨datum⟩) syntax

⟨datum⟩ syntax

⟨constant⟩ syntax

(quote ⟨datum⟩) evaluates to ⟨datum⟩. ⟨Datum⟩ may be any external representation of a Scheme object (see section 3.3). This notation is used to include literal constants in Scheme code.

(quote a) ⇒ a
(quote #(a b c)) ⇒ #(a b c)
(quote (+ 1 2)) ⇒ (+ 1 2)

(quote ⟨datum⟩) may be abbreviated as '⟨datum⟩. The two notations are equivalent in all respects.

'a ⇒ a
'(#(a b c)) ⇒ #(a b c)
'(') ⇒ ()
'('(+ 1 2)) ⇒ (+ 1 2)
'('quote a) ⇒ (quote a)
'''a ⇒ (quote a)

Numerical constants, string constants, character constants, bytector constants, and boolean constants evaluate to themselves; they need not be quoted.

'"abc" ⇒ "abc"
"abc" ⇒ "abc"
'(145932) ⇒ 145932
145932 ⇒ 145932
'#t ⇒ #t
#t ⇒ #t

As noted in section 3.3 it is an error to alter a constant (i.e. the value of a literal expression) using a mutation procedure like set-car! or string-set!.

4.1.3. Procedure calls

⟨(operator) (operand₁) ...⟩ syntax

A procedure call is written by simply enclosing in parentheses expressions for the procedure to be called and the arguments to be passed to it. The operator and operand expressions are evaluated (in an unspecified order) and the resulting procedure is passed the resulting arguments.

(+ 3 4) ⇒ 7
((if #f + *) 3 4) ⇒ 12

A number of procedures are available as the values of variables in the initial environment; for example, the addition and multiplication procedures in the above examples are the values of the variables + and *. New procedures are created by evaluating lambda expressions (see section 4.1.4).

Procedure calls may return any number of values (see values in section 6.10). Most of the procedures defined in this report return one value or, for procedures such as apply, pass on the values returned by a call to one of their arguments. Exceptions are noted in the individual descriptions.

Note: In contrast to other dialects of Lisp, the order of evaluation is unspecified, and the operator expression and the operand expressions are always evaluated with the same evaluation rules.

Note: Although the order of evaluation is otherwise unspecified, the effect of any concurrent evaluation of the operator and operand expressions is constrained to be consistent with some sequential order of evaluation. The order of evaluation may be chosen differently for each procedure call.

Note: In many dialects of Lisp, the empty list, (), is a legitimate expression evaluating to itself. In Scheme, it is an error.

4.1.4. Procedures

(lambda ⟨formals⟩ ⟨body⟩) syntax

Syntax: ⟨Formals⟩ should be a formal arguments list as described below, and ⟨body⟩ should be a sequence of one or more expressions.
Semantics: A lambda expression evaluates to a procedure. The environment in effect when the lambda expression was evaluated is remembered as part of the procedure. When the procedure is later called with some actual arguments, the environment in which the lambda expression was evaluated will be extended by binding the variables in the formal argument list to fresh locations, the corresponding actual argument values will be stored in those locations, and the body of the lambda expression will be evaluated in the extended environment. The results of the last expression in the body will be returned as the results of the procedure call.

\[
\begin{align*}
\text{Call.} & \quad \text{The body will be returned as the results of the procedure} \\
\text{tended environment. The results of the last expression in} & \quad \text{the lambda body of the} \\
\text{argument values will be stored in those locations, and the} & \quad \text{argument list to fresh locations, the corresponding actual} \\
\text{argument values will be stored in those locations, and the} & \quad \text{will be extended by binding the variables in the formal} \\
\text{the body will be returned as the results of the procedure} & \quad \text{will be extended by binding the variables in the formal} \\
\text{call.} & \quad \text{The body will be returned as the results of the procedure call.}
\end{align*}
\]

\[
\begin{align*}
\text{(lambda} & \quad a \text{ procedure} \\
\text{(lambda} & \quad 8 \\
\text{(define reverse-subtract} & \quad 3 \\
\text{(define add4} & \quad 10 \\
\text{Formals}) & \quad \text{should have one of the following forms:}
\end{align*}
\]

- \((\text{variable}_1 \ldots)\): The procedure takes a fixed number of arguments; when the procedure is called, the arguments will be stored in newly allocated locations that are bound to the corresponding variables.

- \((\text{variable})\): The procedure takes any number of arguments; when the procedure is called, the sequence of actual arguments is converted into a newly allocated list, and the list is stored in a newly allocated location that is bound to \((\text{variable})\).

- \((\text{variable}_1 \ldots \text{variable}_n . \text{variable}_{n+1})\): If a space-delimited period precedes the last variable, then the procedure takes \(n\) or more arguments, where \(n\) is the number of formal arguments before the period (it is an error if there is not at least one). The value stored in the binding of the last variable will be a newly allocated list of the actual arguments left over after all the other actual arguments have been matched up against the other formal arguments.

It is an error for a \((\text{variable})\) to appear more than once in \((\text{formal})\).

\[
\begin{align*}
\text{((lambda x x) 3 4 5 6) } & \quad (3 4 5 6) \\
\text{((lambda (x y . z) z) 3 4 5 6) } & \quad (5 6)
\end{align*}
\]

4.1.5. Conditionals

\[
\begin{align*}
\text{(if \langle test \rangle \langle consequent \rangle \langle alternate \rangle) } & \quad \text{syntax} \\
\text{(if \langle test \rangle \langle consequent \rangle) } & \quad \text{syntax}
\end{align*}
\]

Syntax: \((\text{Test}), \langle\text{consequent}\rangle, \text{and \langle alternate\rangle should be expressions.}

Semantics: An if expression is evaluated as follows: first, \((\text{test})\) is evaluated. If it yields a true value (see section 6.3), then \((\text{consequent})\) is evaluated and its values are returned. Otherwise \((\text{alternate})\) is evaluated and its values are returned. If \((\text{test})\) yields a false value and no \((\text{alternate})\) is specified, then the result of the expression is unspecified.

\[
\begin{align*}
\text{(if (> 3 2) 'yes 'no) } & \quad \text{yes} \\
\text{(if (> 2 3) 'yes 'no) } & \quad \text{no} \\
\text{(if (> 3 2) } & \quad 1 \\
\text{(- 3 2) } & \quad 1 \\
\text{(+ 3 2)) } & \quad 1
\end{align*}
\]

4.1.6. Assignments

\[
\begin{align*}
\text{(set! \langle variable \rangle \langle expression \rangle) } & \quad \text{syntax} \\
\text{(Expression) } & \quad \text{evaluated, and the resulting value is stored in the location to which \langle variable \rangle is bound. It is an error if \langle variable \rangle is not bound either in some region enclosing the set! expression or at top level. The result of the set! expression is unspecified.}
\end{align*}
\]

\[
\begin{align*}
\text{(define x 2) } & \quad 3 \\
\text{(+ x 1) } & \quad \text{unspecified} \\
\text{(set! x 4) } & \quad 5
\end{align*}
\]

4.2. Derived expression types

The constructs in this section are hygienic, as discussed in section 4.3. For reference purposes, section 7.3 gives macro definitions that will convert most of the constructs described in this section into the primitive constructs described in the previous section.

4.2.1. Conditionals

\[
\begin{align*}
\text{(cond \langle clause_1 \rangle \langle clause_2 \rangle \ldots) } & \quad \text{auxiliary syntax} \\
\text{else } & \quad \text{auxiliary syntax} \\
\text{=>} & \quad \text{auxiliary syntax}
\end{align*}
\]

Syntax: \((\text{Clauses})\) take one of two forms, either

\[
\begin{align*}
\text{((test) \langle expression_1 \rangle \ldots) } & \quad \text{where \langle test \rangle is any expression, or} \\
\text{((test) => \langle expression \rangle) }
\end{align*}
\]

The last \((\text{clause})\) may be an “else clause,” which has the form
(cond ((> 3 2) 'greater)
     ((< 3 2) 'less))  \(\rightarrow\) greater
(cond ((> 3 3) 'greater)
     ((< 3 3) 'less))  \(\rightarrow\) equal
(cond ((assv 'b '((a 1) (b 2))) => cadr)
     (else #f))  \(\rightarrow\) 2

(case (key) (clause1) (clause2) ...)

Syntax: (Key) may be any expression. Each (clause) should have the form
(((datum1) ...) (expression1) (expression2) ...),
where each (datum) is an external representation of some object. It is an error if any of the (datum) is the same anywhere in the expression. Alternatively, a (clause) may be of the form
(((datum1) ...) \(\Rightarrow\) (expression))
The last (clause) may be an “else clause,” which has one of the forms
(else (expression1) (expression2) ...)
or
(else \(\Rightarrow\) (expression)).

Semantics: A \(\text{case}\) expression is evaluated as follows. (Key) is evaluated and its result is compared against each (datum). If the result of evaluating (key) is equivalent (in the sense of \(\text{eqv}\); see section 6.1) to a (datum), then the expressions in the corresponding (clause) are evaluated in order and the results of the last expression in the (clause) are returned as the results of the \(\text{case}\) expression.

If the result of evaluating (key) is different from every (datum), then if there is an else clause its expressions are evaluated and the results of the last are the results of the \(\text{case}\) expression; otherwise the result of the \(\text{case}\) expression is unspecified.

If the selected (clause) or else clause uses the \(\Rightarrow\) alternate form, then the (expression) is evaluated. It is an error if its value is not a procedure accepting one argument. This procedure returns the values returned by this procedure are returned by the \(\text{case}\) expression.

(case (* 2 3)
 (2 3 5 7) 'prime)
 (1 4 6 8 9) 'composite)) \(\Rightarrow\) composite
(case (car '(c d))
 (a) 'a)
 (b) 'b))  \(\Rightarrow\) unspecified
(case (car '(c d))
 ((a e i o u) 'vowel)
 ((w y) 'semivowel)
 (else \(\Rightarrow\) (lambda (x) x))) \(\Rightarrow\) c

(and (test1) ...)

Syntax
The (test) expressions are evaluated from left to right, and if any expression evaluates to \#f (see section 6.3), then \#f is returned. Any remaining expressions are not evaluated. If all the expressions evaluate to true values, the value of the last expression is returned. If there are no expressions then \#t is returned.

(and (= 2 2) (> 2 1)) \(\Rightarrow\) \#t
(and (= 2 2) (< 2 1)) \(\Rightarrow\) \#f
(and 1 2 'c '(f g)) \(\Rightarrow\) (f g)
(and) \(\Rightarrow\) \#t

(or (test1) ...)

Syntax
The (test) expressions are evaluated from left to right, and if any expression evaluates to \#f (see section 6.3), then \#f is returned. Any remaining expressions are not evaluated. If all expressions evaluate to \#f or if there are no expressions, \#f is returned.

(or (= 2 2) (> 2 1)) \(\Rightarrow\) \#t
(or (= 2 2) (< 2 1)) \(\Rightarrow\) \#t
(or #f #f #f) \(\Rightarrow\) \#f
(or (memq 'b '(a b c))
 (/ 3 0)) \(\Rightarrow\) (b c)

(when (test) (expression1) (expression2) ...)

Syntax
The (test) expression is evaluated, and if it evaluates to a true value, the expressions are evaluated in order. The result of the when expression is unspecified.

The following example outputs 12:
4.2.2. Binding constructs

The binding constructs \texttt{let}, \texttt{let*}, \texttt{letrec}, \texttt{letrec*}, \texttt{let-values}, and \texttt{let*-values} give Scheme a block structure, like Algol 60. The syntax of the first four constructs is identical, but they differ in the regions they establish for their variable bindings. In a \texttt{let} expression, the initial values are computed before any of the variables become bound; in a \texttt{let*} expression, the bindings and evaluations are performed sequentially; while in \texttt{letrec} and \texttt{letrec*} expressions, all the bindings are in effect while their initial values are being computed, thus allowing mutually recursive definitions. The \texttt{let-values} and \texttt{let*-values} constructs are analogous to \texttt{let} and \texttt{let*} respectively, but are designed to handle multiple-valued expressions, binding different identifiers to each returned value.

\texttt{(let \{bindings\} \{body\})} syntax

\textit{Syntax:} \{Bindings\} should have the form

\((\langle\text{variable}\rangle \langle\text{init}\rangle) \ldots\),

where each \{init\} is an expression, and \{body\} should be a sequence of zero or more definitions followed by a sequence of one or more expressions as described in section \ref{sec:expressions}. It is an error for a \{variable\} to appear more than once in the list of variables being bound.

\textit{Semantics:} The \{init\}s are evaluated in the current environment (in some unspecified order), the \{variable\}s are bound to fresh locations holding unspecified values, the \{init\}s are evaluated in the resulting environment, and the values of the last expression of \{body\} are returned. Each binding of a \{variable\} has \{body\} as its region.

See also “named let,” section \ref{sec:binding-contracts}.

\texttt{(let* \{bindings\} \{body\})} syntax

\textit{Syntax:} \{Bindings\} should have the form

\((\langle\text{variable}\rangle \langle\text{init}\rangle) \ldots\),

and \{body\} should be a sequence of zero or more definitions followed by one or more expressions as described in section \ref{sec:expressions}.

\textit{Semantics:} The \texttt{let*} binding construct is similar to \texttt{let}, but the bindings are performed sequentially from left to right, and the region of a binding indicated by \langle\text{variable}\rangle \langle\text{init}\rangle is that part of the \texttt{let*} expression to the right of the binding. Thus the second binding is done in an environment in which the first binding is visible, and so on. The \{variable\}s need not be distinct.

\texttt{(letrec \{bindings\} \{body\})} syntax

\textit{Syntax:} \{Bindings\} should have the form

\((\langle\text{variable}\rangle \langle\text{init}\rangle) \ldots\),

and \{body\} should be a sequence of zero or more definitions followed by one or more expressions as described in section \ref{sec:expressions}. It is an error for a \{variable\} to appear more than once in the list of variables being bound.

\textit{Semantics:} The \{variable\}s are bound to fresh locations holding unspecified values, the \{init\}s are evaluated in the resulting environment (in some unspecified order), each \{variable\} is assigned to the result of the corresponding \{init\}, the \{body\} is evaluated in the resulting environment, and the values of the last expression in \{body\} are returned. Each binding of a \{variable\} has the entire \texttt{letrec} expression as its region, making it possible to define mutually recursive procedures.

\texttt{(letrec \{(even? \lambda (n) \if (zero? n) #t \odds? \lambda (n) \if (zero? n) #f \(even? \(- n 1)))\))}
One restriction on letrec is very important: if it is not possible to evaluate each (init) without assigning or referring to the value of any (variable), it is an error. The restriction is necessary because letrec is defined in terms of a procedure call where a lambda expression binds the (variable)s to the values of the (init)s. In the most common uses of letrec, all the (init)s are lambda expressions and the restriction is satisfied automatically. Another restriction is that the continuation of a (init) should not be invoked more than once.

(letrec* (bindings) (body)) syntax

Syntax: (Bindings) should have the form

(((variable1) (init1)) ...),

and (body) should be a sequence of zero or more definitions followed by one or more expressions as described in section 4.1.4. It is an error for a (variable) to appear more than once in the list of variables being bound.

Semantics: The (variable)s are bound to fresh locations, each (variable) is assigned in left-to-right order to the result of evaluating the corresponding (init), the (body) is evaluated in the resulting environment, and the values of the last expression in (body) are returned. Despite the left-to-right evaluation and assignment order, each binding of a (variable) has the entire letrec* expression as its region, making it possible to define mutually recursive procedures.

If it is not possible to evaluate each (init) without assigning or referring to the value of the corresponding (variable) or the (variable) of any of the bindings that follow it in (bindings), it is an error.

(letrec* ((p
    (lambda (x)
      (+ 1 (q (- x 1)))))
q
    (lambda (y)
      (if (zero? y)
        0
        (+ 1 (p (- y 1)))))
    (x (p 5))
    (y x))
⇒ 5

(let-values (mvbindings) (body)) syntax

Syntax: (Mvbindings) should have the form

(((formals1) (init1)) ...),

where each (init) should be an expression, and (body) should be zero or more definitions followed by a sequence of one or more expressions as described in section 4.1.4. It is an error for a variable to appear more than once in the set of (formals).

Semantics: The (init)s are evaluated in the current environment (in some unspecified order) as if by invoking call-with-values, and the variables occurring in the (formals) are bound to fresh locations holding the values returned by the (init)s, where the (formals) are matched to the return values in the same way that the (formals) in a lambda expression are matched to the arguments in a procedure call. Then, the (body) is evaluated in the extended environment, and the values of the last expression of (body) are returned. Each binding of a (variable) has (body) as its region.

It is an error if the (formals) do not match the number of values returned by the corresponding (init).

(let-values (((root rem) (exact-integer-sqrt 32)))
 (* root rem)  ⇒ 35

(let**-values (mvbindings) (body)) syntax

Syntax: (Mvbindings) should have the form

(((formals) (init)) ...),

and (body) should be a sequence of zero or more definitions followed by one or more expressions as described in section 4.1.4. In each (formals), it is an error if any variable appears more than once.

Semantics: The let-values* construct is similar to let-values, but the (init)s are evaluated and bindings created sequentially from left to right, with the region of the bindings of each (formals) including the (init)s to its right as well as (body). Thus the second (init) is evaluated in an environment in which the first set of bindings is visible and initialized, and so on.

(let (((a 'a) (b 'b) (x 'x) (y 'y))
    (let**-values (((a b) (values x y))
                 ((x y) (values a)))
    (list a b x y)))  ⇒ (x y x y)

4.2.3. Sequencing

Both of Scheme’s sequencing constructs are named begin, but the two have slightly different forms and uses:

(begin (expression or definition) ...)

Syntax

This form of begin may appear as part of a (body), or at the (top-level), or directly nested in a begin that is itself of this form. It causes the contained expressions and definitions to be evaluated exactly as if the enclosing begin construct were not present.

Rationale: This form is commonly used in the output of macros (see section 4.3) which need to generate multiple definitions and splice them into the context in which they are expanded.
\begin{align*}
\text{begin} \langle \text{expression}_1 \rangle \langle \text{expression}_2 \rangle \ldots \rangle \quad \text{syntax}
\end{align*}

This form of \text{begin} can be used as an ordinary expression. The \langle \text{expression} \rangle s are evaluated sequentially from left to right, and the values of the last \langle \text{expression} \rangle are returned. This expression type is used to sequence side effects such as assignments or input and output.

\begin{verbatim}
(define x 0)
(and (= x 0)
  (begin (set! x 5)
    (+ x 1)) \Rightarrow 6

(begin (display "4 plus 1 equals ")
  (display (+ 4 1))) \Rightarrow \text{unspecified}
  \text{and prints} 4 plus 1 equals 5
\end{verbatim}

4.2.4. Iteration

\begin{verbatim}
(do ((\langle variable \rangle \langle init \rangle \langle step \rangle))
  \langle command \rangle \ldots)
  \langle\text{test} \rangle \langle\text{expression} \rangle \ldots\rangle
\end{verbatim}

A \textit{do} expression is an iteration construct. It specifies a set of variables to be bound, how they are to be initialized at the start, and how they are to be updated on each iteration. When a termination condition is met, the loop exits after evaluating the \langle \text{expression} \rangle s.

A \textit{do} expression is evaluated as follows: The \langle \text{init} \rangle expressions are evaluated (in some unspecified order), the \langle \text{variable} \rangle s are bound to fresh locations, the results of the \langle \text{init} \rangle expressions are stored in the bindings of the \langle \text{variable} \rangle s, and then the iteration phase begins.

Each iteration begins by evaluating \langle test \rangle; if the result is false (see section 6.3), then the \langle command \rangle expressions are evaluated in order for effect, the \langle step \rangle expressions are evaluated in some unspecified order, the \langle variable \rangle s are bound to fresh locations, the results of the \langle step \rangle s are stored in the bindings of the \langle variable \rangle s, and the next iteration begins.

If \langle test \rangle evaluates to a true value, then the \langle expression \rangle s are evaluated from left to right and the values of the last \langle expression \rangle are returned. If no \langle expression \rangle s are present, then the value of the \textit{do} expression is unspecified.

The region of the binding of a \langle variable \rangle consists of the entire \textit{do} expression except for the \langle init \rangle s. It is an error for a \langle variable \rangle to appear more than once in the list of \textit{do} variables.

A \langle step \rangle may be omitted, in which case the effect is the same as if \langle variable \rangle \langle init \rangle \langle variable \rangle had been written instead of \langle variable \rangle \langle init \rangle.

\begin{verbatim}
(do ((vec (make-vector 5))
  (i 0 (+ i 1)))
  (= i 5) vec)
\end{verbatim}

4.2.5. Delayed evaluation

\begin{verbatim}
(delay \langle expression \rangle) \quad \text{lazy library syntax}
\end{verbatim}

The \textit{delay} construct is used together with the procedure \textit{force} to implement \textit{lazy evaluation} or \textit{call by need}. \langle delay \langle expression \rangle \rangle returns an object called a \textit{promise} which at some point in the future may be asked (by the \textit{force} procedure) to evaluate \langle expression \rangle, and deliver the resulting value. The effect of \langle expression \rangle returning multiple values is unspecified.

\begin{verbatim}
(lazy \langle expression \rangle) \quad \text{lazy library syntax}
\end{verbatim}

The \textit{lazy} construct is similar to \textit{delay}, but it is an error for its argument not to evaluate to a promise. The returned promise, when forced, will evaluate to whatever the original promise would have evaluated to if it had been forced.

\begin{verbatim}
(force \langle promise \rangle) \quad \text{lazy library procedure}
\end{verbatim}

The \textit{force} procedure forces the value of a \textit{promise} created by \textit{delay} or \textit{lazy}. If no value has been computed for the promise, then a value is computed and returned. The value of the promise is cached (or “memoized”) so that if it is forced a second time, the previously computed value is returned.
The following example is a mechanical transformation of a lazy stream-filtering algorithm into Scheme. Each call to a constructor is wrapped in `delay`, and each argument passed to a deconstructor is wrapped in `force`. The use of `(lazy ...)` instead of `(delay (force ...))` around the body of the procedure ensures that an ever-growing sequence of pending promises does not exhaust the heap.

```
(define (stream-filter p? s)
  (lazy
    (if (null? (force s))
        (delay '())
        (let ((h (car (force s)))
              (t (cdr (force s))))
            (if (p? h)
                (delay (cons h (stream-filter p? t)))
                (stream-filter p? t))))))
```

```
(head (tail (tail (stream-filter odd? integers))))
⇒ 5
```

The following examples are not intended to illustrate good programming style, as `delay`, `lazy`, and `force` are mainly intended for programs written in the functional style. However, they do illustrate the property that only one value is computed for a promise, no matter how many times it is forced.

```
(define count 0)
(define p
  (delay (begin (set! count (+ count 1))
              (if (> count x)
                  count
                  (force p)))))
(define x 5)
p
⇒ a promise
(force p)
⇒ 6
p
⇒ a promise, still
(begin (set! x 10)
  (force p))
⇒ 6
```

Various extensions to this semantics of `delay`, `force` and `lazy` are supported in some implementations:

- Calling `force` on an object that is not a promise may simply return the object.
- It may be the case that there is no means by which a promise can be operationally distinguished from its forced value. That is, expressions like the following may evaluate to either `#t` or to `#f`, depending on the implementation:

```
(eqv? (delay 1) 1)   ⇒ unspecified
(pair? (delay (cons 1 2))) ⇒ unspecified
```

- Some implementations may implement “implicit forcing,” where the value of a promise is forced by primitive procedures like `cdr` and `+`:

```
(+ (delay (* 3 7)) 13)  ⇒ 34
```

The `eager` procedure returns a promise which, when forced, will return `obj`. It is similar to `delay`, but does not delay its argument: it is a procedure rather than syntax.

### 4.2.6. Dynamic bindings

```
(make-parameter init)
(make-parameter init converter)
```

Returns a newly allocated `parameter object`, which is a procedure that accepts zero arguments and returns the value associated with the parameter object. Initially, this value is the value of `(converter init)`, or of `init` if the conversion procedure `converter` is not specified. The associated value can be temporarily changed using `parameterize`, which is described below.

The effect of passing arguments to a `parameter object` is implementation-dependent.

```
(parameterize ((⟨param1⟩ ⟨value1⟩) ...)
  ⟨body⟩)
```

A `parameterize` expression is used to change the values returned by specified parameter objects during the evaluation of the body. It is an error if the value of any ⟨param⟩ expression is not a parameter object. The ⟨param⟩ and ⟨value⟩ expressions are evaluated in an unspecified order. The ⟨body⟩ is evaluated in a dynamic environment in which calls to the parameters return the results of passing the corresponding values to the conversion procedure specified when the parameters were created. Then the previous values of the parameters are restored without passing them to
the conversion procedure. The results of the last expression in the (body) are returned as the results of the entire parameterize expression.

Note: If the conversion procedure is not idempotent, the results of (parameterize ((x (x))) ...), which appears to bind the parameter x to its current value, may not be what the user expects.

If an implementation supports multiple threads of execution, then parameterize must not change the associated values of any parameters in any thread other than the current thread and threads created inside (body).

Parameter objects can be used to specify configurable settings for a computation without the need to pass the value to every procedure in the call chain explicitly.

(define radix
take that binds the raised object to ⟨tions.
See section 6.11 for a more complete discussion of excep-
is that of the guard raise-continuable
nal call to raised object within the dynamic environment of the origi-
clause, then else ury ⟨cond explicit
and dynamic environment of the guard ⟨cond clause within the scope of that binding, evaluates the clauses as if they were the clauses of a cond expression. That implicit cond expression is evaluated with the continuation and dynamic environment of the guard expression. If every (cond clause)’s (test) evaluates to #f and there is no else clause, then raise-continuable is re-invoked on the raised object within the dynamic environment of the original call to raise except that the current exception handler is that of the guard expression.

See section 6.11 for a more complete discussion of exceptions.

4.2.7. Exception Handling

(guard ((variable) ⟨syntax
(cond clause1) (cond clause2) ...⟩ (body))

Syntax: Each (cond clause) is as in the specification of cond.

Semantics: The (body) is evaluated with an exception handler that binds the raised object to (variable) and, within the scope of that binding, evaluates the clauses as if they were the clauses of a cond expression. That implicit cond expression is evaluated with the continuation and dynamic environment of the guard expression. If every (cond clause)’s (test) evaluates to #f and there is no else clause, then raise-continuable is re-invoked on the raised object within the dynamic environment of the original call to raise except that the current exception handler is that of the guard expression.

4.2.8. Quasiquotation

(quasiquote ⟨qq template⟩) syntax
`⟨qq template⟩` auxiliary syntax
unquote auxiliary syntax
unquote-splicing auxiliary syntax

“Backquote” or “quasiquote” expressions are useful for constructing a list or vector structure when some but not all of the desired structure is known in advance. If no commas appear within the ⟨qq template⟩, the result of evaluating `⟨qq template⟩` is equivalent to the result of evaluating `⟨qq template⟩`. If a comma appears within the ⟨qq template⟩, however, the expression following the comma is evaluated (“unquoted”) and its result is inserted into the structure instead of the comma and the expression. If a comma appears followed immediately by an at-sign (\@), then it is an error if the following expression does not evaluate to a list; the opening and closing parentheses of the list are then “stripped away” and the elements of the list are inserted in place of the comma at-sign expression sequence. A comma at-sign should only appear within a list or vector ⟨qq template⟩.

```scheme
'(list ,(+ 1 2) 4) ⇒ (list 3 4)
(let ((name 'a)) '(list ,name ,name)) ⇒ (list a (quote a))
'((foo ,(- 10 3)) ,@(cdr '(c)) . ,(car '(cons))) ⇒ ((foo 7) . cons)
'((1 2) 3 4 five 6)
(let ((a 3)) '((1 2) ,a ,4 ,'five 6))
```

Quasiquote expressions may be nested. Substitutions are made only for unquoted components appearing at the same nesting level as the outermost backquote. The nesting level increases by one inside each successive quasiquotation, and decreases by one inside each unquotation.

```scheme
'(a `(b ,(+ 1 2) ,(foo ,(+ 1 3) d) e) f) ⇒ (a `(b ,(+ 1 2) ,(foo 4 d) e) f)
(let ((name1 'x) (name2 'y))
  '(a `(b ,name1 ,name2 d) e)) ⇒ (a `(b ,x ,y d) e)
```

A quasiquote expression may return either fresh, mutable objects or literal structure for any structure that is constructed at run time during the evaluation of the expression. Portions that do not need to be rebuilt are always literal. Thus,

```scheme
(let ((a 3)) `((1 2) ,a ,4 ,five 6))
```

may be equivalent to either of the following expressions:

```scheme
`((1 2) 3 4 five 6)
```
(let ((a 3))
  (cons '1 2)
  (cons a (cons 4 (cons 'five '(6))))))

However, it is not equivalent to this expression:

(let ((a 3)) (list (list 1 2) a 'four 'five 6))

The two notations `'(qq template) and (quasiquote (qq template)) are identical in all respects. `expression is identical to (unquote (expression)), and @expression is identical to (unquote-splicing (expression)). The external syntax generated by write for two-element lists whose car is one of these symbols may vary between implementations.

(quasiquote (list (unquote (+ 1 2)) 4))
⇒ (list 3 4)
'(quasiquote (list (unquote (+ 1 2)) 4))
⇒ ' (list ,(+ 1 2) 4)
i.e., (quasiquote (list (unquote (+ 1 2)) 4))

It is an error if any of the identifiers quasiquote, unquote, or unquote-splicing appear in positions within a (qq template) otherwise than as described above.

### 4.2.9. Case-lambda

(case-lambda (clause1) (clause2) ...)

case-lambda library syntax

**Syntax:** Each (clause) should be of the form ((formals) (body)), where (formals) and (body) have the same syntax as in a lambda expression.

**Semantics:** A case-lambda expression evaluates to a procedure that accepts a variable number of arguments and is lexically scoped in the same manner as a procedure resulting from a lambda expression. When the procedure is called, the first (clause) for which the arguments agree with (formals) is selected, where agreement is specified as for the (formals) of a lambda expression. The variables of (formals) are bound to fresh locations, the values of the arguments are stored in those locations, the (body) is evaluated in the extended environment, and the results of (body) are returned as the results of the procedure call.

It is an error for the arguments not to agree with the (formals) of any (clause).

(define range
  (case-lambda
    ((e) (range 0 e))
    ((b e) (do ((r '()) (cons e r))
               (e (- e 1) (- e 1)))
               ((< e b) r))))

(range 3)  ⇒ (0 1 2)
(range 3 5)  ⇒ (3 4)

### 4.3. Macros

Scheme programs can define and use new derived expression types, called macros. Program-defined expression types have the syntax

((keyword) (datum) ...)

where (keyword) is an identifier that uniquely determines the expression type. This identifier is called the syntactic keyword, or simply keyword, of the macro. The number of the (datum)s, and their syntax, depends on the expression type.

Each instance of a macro is called a use of the macro. The set of rules that specifies how a use of a macro is transcribed into a more primitive expression is called the transformer of the macro.

The macro definition facility consists of two parts:

- A set of expressions used to establish that certain identifiers are macro keywords, associate them with macro transformers, and control the scope within which a macro is defined, and
- A pattern language for specifying macro transformers.

The syntactic keyword of a macro may shadow variable bindings, and local variable bindings may shadow keyword bindings:

- If a macro transformer inserts a binding for an identifier (variable or keyword), the identifier will in effect be renamed throughout its scope to avoid conflicts with other identifiers. Note that a define at top level may or may not introduce a binding; see section 5.2
- If a macro transformer inserts a free reference to an identifier, the reference refers to the binding that was visible where the transformer was specified, regardless of any local bindings that surround the use of the macro.

In consequence, all macros defined using the pattern language are “hygienic” and “referentially transparent” and thus preserve Scheme’s lexical scoping.

### 4.3.1. Binding constructs for syntactic keywords

The let-syntax and letrec-syntax binding constructs are analogous to let and letrec, but they bind syntactic keywords to macro transformers instead of binding variables to locations that contain values. Syntactic keywords may also be bound at top level or elsewhere with define-syntax; see section 5.3

(let-syntax (bindings) (body))

**Syntax:** (Bindings) should have the form
Each ⟨keyword⟩ is an identifier, each ⟨transformer spec⟩ is an instance of syntax-rules, and ⟨body⟩ should be a sequence of one or more definitions followed by one or more expressions. It is an error for a ⟨keyword⟩ to appear more than once in the list of keywords being bound.

Semantics: The ⟨body⟩ is expanded in the syntactic environment obtained by extending the syntactic environment of the let-syntx expression with macros whose keywords are the ⟨keyword⟩s, bound to the specified transformers. Each binding of a ⟨keyword⟩ has ⟨body⟩ as its region.

(let-syntax ((when (syntax-rules ()
  (when test stmt1 stmt2 ...)
  (if test
    (begin stmt1
    stmt2 ...)()))))
(let ((if #t))
  (when if (set! if 'now))
  if)) ⇒ now
(let ((x 'outer))
  (let-syntax ((m (syntax-rules () ((m) x))))
    (let ((x 'inner))
      (m)))) ⇒ outer

(letrec-syntax (bindings) (body)) syntax

Syntax: Same as for let-syntx.

Semantics: The ⟨body⟩ is expanded in the syntactic environment obtained by extending the syntactic environment of the letrec-syntax expression with macros whose keywords are the ⟨keyword⟩s, bound to the specified transformers. Each binding of a ⟨keyword⟩ has the ⟨transformer spec⟩ as well as the ⟨body⟩ within its region, so the transformers can transcribe expressions into uses of the macros introduced by the letrec-syntax expression.

(letrec-syntax
  ((my-or (syntax-rules ()
      (my-or #f)
      (my-or e) e)
      (my-or ei e2 ...)
      (let ((temp el))
        (if temp
          temp
          (my-or e2 ...))))))
(let ((x #f)
  (y 7)
  (temp 8)
  (let odd?)
  (if even?)
  (my-or x
    (let temp)
    (if y)
    y))) ⇒ 7

4.3.2. Pattern language

A ⟨transformer spec⟩ has one of the following forms:

(syntax-rules ((literal) ...) syntax
  (syntax rule) ...)
(syntax-rules (ellipsis) ((literal) ...) syntax
  (syntax rule) ...)

Auxiliary syntax

Syntax: It is an error if any of the ⟨literal⟩s, or the ⟨ellipsis⟩ in the second form, is not an identifier. It is also an error if ⟨syntax rule⟩ is not of the form

  (pattern) (template)

The ⟨pattern⟩ in a ⟨syntax rule⟩ is a list ⟨pattern⟩ whose first element is an identifier.

A ⟨pattern⟩ is either an identifier, a constant, or one of the following

  (pattern) ...
  (pattern) (pattern) ...
  (pattern) ...
  (pattern) (ellipsis) (pattern) ...
  (pattern) ...
  (pattern) ...
  (pattern) (ellipsis) (pattern) ...

and a template is either an identifier, a constant, or one of the following

  (element) ...
  (element) (element) ...
  (template)
  (ellipsis) (template)
  #(element) ...

where an ⟨element⟩ is a ⟨template⟩ optionally followed by an ⟨ellipsis⟩. An ⟨ellipsis⟩ is the identifier specified in the second form of syntax-rules, or the default identifier ... (three consecutive periods) otherwise.

Semantics: An instance of syntax-rules produces a new macro transformer by specifying a sequence of hygienic rewrite rules. A use of a macro whose keyword is associated with a transformer specified by syntax-rules is matched against the patterns contained in the ⟨syntax rule⟩s, beginning with the leftmost ⟨syntax rule⟩. When a match is found, the macro use is transcribed hygienically according to the template.

An identifier appearing within a ⟨pattern⟩ may be an underscore (_), a literal identifier listed in the list of ⟨literal⟩s, or the ⟨ellipsis⟩. All other identifiers appearing within a ⟨pattern⟩ are pattern variables.

The keyword at the beginning of the pattern in a ⟨syntax rule⟩ is not involved in the matching and is considered neither a pattern variable nor a literal identifier.

Pattern variables match arbitrary input elements and are used to refer to elements of the input in the template. It
is an error for the same pattern variable to appear more than once in a (pattern).

Underscores also match arbitrary input elements but are not pattern variables and so cannot be used to refer to those elements. If an underscore appears in the (literal)'s list, then that takes precedence and underscores in the (pattern) match as literals. Multiple underscores may appear in a (pattern).

Identifiers that appear in ((literal) ...) are interpreted as literal identifiers to be matched against corresponding elements of the input. An element in the input matches a literal identifier if and only if it is an identifier and either both its occurrence in the macro expression and its occurrence in the macro definition have the same lexical binding, or the two identifiers are equal and both have no lexical binding.

A subpattern followed by ⟨ellipsis⟩ can match zero or more elements of the input, unless (ellipsis) appears in the (literal)'s, in which case it is matched as a literal.

More formally, an input expression \( E \) matches a pattern \( P \) if and only if:

- \( P \) is an underscore (\_),
- \( P \) is a non-literal identifier; or
- \( P \) is a literal identifier and \( E \) is an identifier with the same binding; or
- \( P \) is a list \((P_1 \ldots P_n)\) and \( E \) is a list of \( n \) elements that match \( P_1 \) through \( P_n \), respectively; or
- \( P \) is an improper list \((P_1 P_2 \ldots P_n \ P_{n+1})\) and \( E \) is a list or improper list of \( n \) or more elements that match \( P_1 \) through \( P_n \), respectively, and whose \( n \)th tail matches \( P_{n+1} \); or
- \( P \) is of the form \((P_1 \ldots P_{e-1} P_e \ (ellipsis) \ P_{m+1} \ldots P_n)\) where \( E \) is a proper list of \( n \) elements, the first \( e-1 \) of which match \( P_1 \) through \( P_{e-1} \), respectively, whose next \( m-k \) elements each match \( P_e \), whose remaining \( n-m \) elements match \( P_{m+1} \) through \( P_n \); or
- \( P \) is of the form \((P_1 \ldots P_{e-1} P_e \ (ellipsis) \ P_{m+1} \ldots P_n)\) where \( E \) is an list or improper list of \( n \) elements, the first \( e-1 \) of which match \( P_1 \) through \( P_{e-1} \), whose next \( m-k \) elements each match \( P_e \), whose remaining \( n-m \) elements match \( P_{m+1} \) through \( P_n \), and whose \( n \)th and final cdr matches \( P_e \); or
- \( P \) is a vector of the form \#(\(P_1 \ldots P_n\)) and \( E \) is a vector of \( n \) elements that match \( P_1 \) through \( P_n \); or
- \( P \) is of the form \#(\(P_1 \ldots P_{e-1} P_e \ (ellipsis) \ P_{m+1} \ldots P_n\)) where \( E \) is a vector of \( n \) elements the first \( e-1 \) of which match \( P_1 \) through \( P_{e-1} \), whose next \( m-k \) elements each match \( P_e \), and whose remaining \( n-m \) elements match \( P_{m+1} \) through \( P_n \); or
- \( P \) is a constant and \( E \) is equal to \( P \) in the sense of the equal? procedure.

It is an error to use a macro keyword, within the scope of its binding, in an expression that does not match any of the patterns.

When a macro use is transcribed according to the template of the matching (syntax rule), pattern variables that occur in the template are replaced by the elements they match in the input. Pattern variables that occur in subpatterns followed by one or more instances of the identifier (ellipsis) are allowed only in subtemplates that are followed by as many instances of (ellipsis). They are replaced in the output by all of the elements they match in the input, distributed as indicated. It is an error if the output cannot be built up as specified.

Identifiers that appear in the template but are not pattern variables or the identifier (ellipsis) are inserted into the output as literal identifiers. If a literal identifier is inserted as a free identifier then it refers to the binding of that identifier within whose scope the instance of syntax-rules appears. If a literal identifier is inserted as a bound identifier then it is in effect renamed to prevent inadvertent captures of free identifiers.

A template of the form ((ellipsis) (template)) is identical to (template), except that ellipses within the template have no special meaning. That is, any ellipses contained within (template) are treated as ordinary identifiers. In particular, the template ((ellipsis) (ellipsis)) produces a single (ellipsis). This allows syntactic abstractions to expand into code containing ellipses.

```scheme
(define-syntax be-like-begin
  (syntax-rules ()
    ((be-like-begin name)
     (define-syntax name
      (syntax-rules ()
        ((name expr (\ldots \ldots)))
        (begin expr (\ldots \ldots))))))

    (be-like-begin sequence)
    (sequence 1 2 3 4) => 4)
)
```

As an example, if let and cond are defined as in section 7.3 then they are hygienic (as required) and the following is not an error.

```scheme
(let ((\=> #f))
  (cond (#t => 'ok))) => ok
```

The macro transformer for cond recognizes => as a local variable, and hence an expression, and not as the top-level identifier =>, which the macro transformer treats as a syntactic keyword. Thus the example expands into

```scheme
(let ((\=> #f))
  (if #t (begin => 'ok)))
```
instead of
   (let ((=> #f))
       (let ((temp #t))
           (if temp ('ok temp)))))
which would result in an invalid procedure call.

### 5. Program structure

#### 5.1. Programs

A Scheme program consists of a sequence of program parts: expressions, definitions, syntax definitions, record type definitions, imports, cond-expands, and includes. A collection of program parts may be encapsulated in a library to be reused by multiple programs. Expressions are described in chapter 4; the other program parts, as well as libraries, are the subject of the present chapter.

Programs and libraries are typically stored in files, although programs can be entered interactively to a running Scheme system, and other paradigms are possible. Implementations which store libraries in files should document the mapping from the name of a library to its location in the file system.

Program parts other than expressions that are present at the top level of a program can be interpreted declaratively. They cause bindings to be created in the top level environment or modify the value of existing top-level bindings. The initial (or “top level”) Scheme environment is empty except for import, so further bindings can only be introduced with import.

Expressions occurring at the top level of a program are interpreted imperatively; they are executed in order when the program is invoked or loaded, and typically perform some kind of initialization.

At the top level of a program (begin ⟨form1⟩ ...) is equivalent to the sequence of expressions, definitions, and syntax definitions in the begin. Macros can expand into such begins.

Implementations may provide an interactive session called a REPL (Read-Eval-Print Loop), where Scheme program parts can be entered and evaluated one at a time. For convenience and ease of use, the “top-level” Scheme environment in a REPL must not be not empty, but must start out with variables bound to locations containing at least the bindings provided by the base library. This library includes the core syntax of Scheme and generally useful procedures that manipulate data. For example, the variable abs is bound to a procedure of one argument that computes the absolute value of a number, and the variable + is bound to a procedure that computes sums. The full list of (scheme base) bindings can be found in Appendix A.

#### 5.2. Definitions

Definitions are valid in some, but not all, contexts where expressions are allowed. They are valid only at the top level of a ⟨program⟩ and at the beginning of a ⟨body⟩.
In a \( \langle \text{body} \rangle \) (begin \{definition_1\} ... ) is equivalent to the sequence of definitions \( \langle \text{definition}_1 \rangle \) .... Macros can expand into such begins.

A definition takes one of the following forms:

- \( \langle \text{define} \ (\text{variable}) \ (\text{expression}) \rangle \)
- \( \langle \text{define} \ (\langle \text{variable} \rangle \ (\langle \text{formals} \rangle) \ (\text{body}) \rangle \)

(Formals) should be either a sequence of zero or more variables, or a sequence of one or more variables followed by a space-delimited period and another variable (as in a space-delimited period). This form is equivalent to

\[
\langle \text{define} \ (\langle \text{variable} \rangle) \\
\quad \langle \text{lambda} \ (\langle \text{formals} \rangle) \ (\text{body}) \rangle \rangle.
\]

- \( \langle \text{define} \ (\langle \text{variable} \rangle \ . \ (\text{formal}) \ (\text{body}) \rangle \)

(Formal) should be a single variable. This form is equivalent to

\[
\langle \text{define} \ (\langle \text{variable} \rangle) \\
\quad \langle \text{lambda} \ (\langle \text{formal} \rangle) \ (\text{body}) \rangle \rangle.
\]

5.2.1. Top level definitions

At the top level of a program, a definition

\[
\langle \text{define} \ (\text{variable}) \ (\text{expression}) \rangle
\]

has essentially the same effect as the assignment expression

\[
\langle \text{set!} \ (\text{variable}) \ (\text{expression}) \rangle
\]

if \( \langle \text{variable} \rangle \) is bound to a non-syntax value. However, if \( \langle \text{variable} \rangle \) is not bound, or is bound to a syntax definition (see below), then the definition will bind \( \langle \text{variable} \rangle \) to a new location before performing the assignment, whereas it would be an error to perform a \langle \text{set!} \rangle on an unbound variable.

\[
\langle \text{define add3} \\
\quad \langle \text{lambda} \ (x) \ (+ \ x \ 3) \rangle \rangle \\
\quad (\text{add3} \ 3) \quad \Rightarrow \ 6 \\
\quad \langle \text{define first car} \\
\quad \langle \text{first} \ (\langle 1 \ 2 \rangle) \rangle \rangle \quad \Rightarrow \ 1
\]

Implementations are permitted to provide an initial environment in which all possible variables are bound to locations, most of which contain unspecified values. Top level definitions in such an implementation are truly equivalent to assignments.

5.2.2. Internal definitions

Definitions may occur at the beginning of a \( \langle \text{body} \rangle \) (that is, the body of a \text{lambda}, \text{let}, \text{let*}, \text{letrec}, \text{letrec*}, \text{let-values}, \text{let-values*}, \text{let-syntax}, \text{letrec-syntax}, \text{parameterize}, \text{guard}, \text{or case-lambda} expression or that of a definition of an appropriate form). Such definitions are known as \text{internal definitions} as opposed to the top-level definitions described above. The variable defined by an internal definition is local to the \( \langle \text{body} \rangle \). That is, \( \langle \text{variable} \rangle \) is bound rather than assigned, and the region of the binding is the entire \( \langle \text{body} \rangle \). For example,

\[
\langle \text{let} \ ((x \ 5)) \\
\quad \langle \text{define foo} \ (\langle \text{lambda} \ (y) \ (\text{bar x y}) \rangle) \\
\quad \langle \text{define bar} \ (\langle \text{lambda} \ (a \ b) \ (+ \ (* \ a \ b) \ a) \rangle) \\
\quad (\text{foo} \ (+ \ x \ 3)) \rangle \quad \Rightarrow \ 45
\]

An expanded \( \langle \text{body} \rangle \) containing internal definitions can always be converted into a completely equivalent \text{letrec*} expression. For example, the \langle \text{let} \rangle expression in the above example is equivalent to

\[
\langle \text{let} \ ((x \ 5)) \\
\quad \langle \text{letrec*} \ ((\text{foo} \ (\langle \text{lambda} \ (y) \ (\text{bar x y}) \rangle) \\
\quad \quad \langle \text{bar} \ (\langle \text{lambda} \ (a \ b) \ (+ \ (* \ a \ b) \ a) \rangle) \\
\quad \quad (\text{foo} \ (+ \ x \ 3)) \rangle) \rangle
\]

Just as for the equivalent \text{letrec*} expression, it is an error if it is not possible to evaluate each \langle \text{expression} \rangle of every internal definition in a \( \langle \text{body} \rangle \) without assigning or referring to the value of the corresponding \langle \text{variable} \rangle or the \langle \text{variable} \rangle of any of the definitions that follow it in \( \langle \text{body} \rangle \).

It is an error to define the same identifier more than once in the same \( \langle \text{body} \rangle \).

Wherever an internal definition may occur, \langle \text{begin} \ \langle \text{definition}_1 \rangle \ ... \rangle \) is equivalent to the sequence of definitions that form the body of the \langle \text{begin} \rangle.

5.2.3. Multiple-value definitions

The construct \text{define-values} introduces new definitions like \text{define}, but can create multiple definitions from a single expression returning multiple values. It is allowed wherever \text{define} is allowed.

\[
\langle \text{define-values} \ (\langle \text{formals} \rangle) \ (\langle \text{expression} \rangle) \rangle
\]

It is an error if a variable appears more than once in the set of \langle \text{formals} \rangle.

\textit{Semantics:} \langle \text{Expression} \rangle \textit{is evaluated}, and the \langle \text{formals} \rangle are bound to the return values in the same way that the \langle \text{formals} \rangle in a \text{lambda} expression are matched to the arguments in a procedure call.

\[
\langle \text{let} () \\
\quad \langle \text{define-values} \ (x \ y) \ (\langle \text{values} \ 1 \ 2 \rangle) \\
\quad (+ \ x \ y)) \rangle \quad \Rightarrow \ 3
\]
5.3. Syntax definitions

Syntax definitions are valid wherever definitions are. They have the following form:

```scheme
(define-syntax (keyword) (transformer spec))
```

(Keyword) is an identifier, and the (transformer spec) should be an instance of syntax-rules. If the define-syntax occurs at the top level, then the top-level syntactic environment is extended by binding the (keyword) to the specified transformer, but existing references to any top-level binding for (keyword) remain unchanged. Otherwise, it is an *internal syntax definition*, and is local to the (body) in which it is defined.

```scheme
(let ((x 1) (y 2))
  (define-syntax swap!
    (syntax-rules ()
      ((a b) (set! b tmp)))))

(swap! x y)
(list x y)) => (2 1)
```

Macros can expand into definitions in any context that permits them. However, it is an error for a definition to define an identifier whose binding has to be known in order to determine the meaning of the definition itself, or of any preceding definition that belongs to the same group of internal definitions. Similarly, it is an error for an internal definition to define an identifier whose binding has to be known in order to determine the boundary between the internal definitions and the expressions of the body it belongs to. For example, the following are errors:

```scheme
(define define 3)
(begin (define begin list))
(let-syntax
  (((foo proc args ...) body ...)
    (define proc
      (lambda (args ...) body ...)))
  (let ((x 3))
    (foo (plus x y) (+ x y))
    (define foo x)
    (plus foo x)))
```

5.4. Record type definitions

*Record type definitions* are used to introduce new data types, called *record types*. The values of a record type are called *records* and are aggregations of zero or more *fields*, each of which holds a single location. A predicate, a constructor, and field accessors and mutators are defined for each record type. Record type definitions are valid wherever definitions are.

```scheme
(define-record-type (name)
  (constructor) (pred) (field) ...)
```

*Syntax:* (name) and (pred) should be identifiers. The (constructor) should be of the form

```scheme
((constructor name) (field name) ...)
```

and each (field) should be either of the form

```scheme
((field name) (accessor name))
```
or of the form

```scheme
((field name) (accessor name) (modifier name))
```

It is an error for the same identifier to occur more than once as a field name.

define-record-type is generative: each use creates a new record type that is distinct from all existing types, including Scheme’s predefined types and other record types — even record types of the same name or structure.

An instance of define-record-type is equivalent to the following definitions:

- (name) is bound to a representation of the record type itself. This may be a run-time object or a purely syntactic representation.
- (constructor name) is bound to a procedure that takes as many arguments as there are (field name)s in the ((constructor name) ...) subexpression and returns a new record of type (name). Fields whose names are listed with (constructor name) have the corresponding argument as their initial value. The initial values of all other fields are unspecified. It is an error for a field name to appear in (constructor) but not as a (field name).
- (pred) is bound to a predicate that returns #t when given a value returned by the procedure bound to (constructor name) and #f for everything else.
- Each (accessor name) is bound to a procedure that takes a record of type (name) and returns the current value of the corresponding field. It is an error to pass an accessor a value which is not a record of the appropriate type.
- Each (modifier name) is bound to a procedure that takes a record of type (name) and a value which becomes the new value of the corresponding field; an unspecified value is returned. It is an error to pass a modifier a first argument which is not a record of the appropriate type.

For instance, the following definition
(define-record-type <pare>
  (kons x y)
  pare?
  (x kar set-kar!)
  (y kdr))

defines kons to be a constructor, kar and kdr to be ac-

5.5. Libraries

Libraries provide a way to organize Scheme programs into

5.5.1. Library Syntax

A library definition takes the following form:

(define-library <library name>
  <library declaration> ...)

(library name) is a list whose members are identifiers and

An export declaration specifies a list of identifiers which

• (export (export spec) ...)
• (import (import set) ...)
• (begin (command or definition) ...)  
• (include <filename1> <filename2> ...)  
• (include-ci <filename1> <filename2> ...)  
• (cond-expand (cond-expand clause) ...)  

An export declaration specifies a list of identifiers which can

In an (export spec), an (identifier) names a single bind-

• (identifier)
• (rename (identifier1) (identifier2))

In an (export spec), an (identifier) names a single bind-

• (library name)
• (rename (import set1) ((identifier2) (identifier)) ...)  
• (prefix (import set) (identifier))  
• (only (import set) (identifier) ...)  
• (except (import set) (identifier) ...)  

In the first form, all of the identifiers in the named library’s export

• rename modifies the given (import set), replacing each

• only produces a subset of the given (import set), in-

• except produces a subset of the given (import set), ex-

The top level of a program may also include import decla-

define-syntx or set!. However, a REPL should permit these actions.

The begin, include, and include-ci declarations are used to specify the commands and definitions that make up the body of the library. The begin declaration takes a list of expressions and definitions to be spliced literally, analogous to the top-level begin. Both the include and include-ci declarations take one or more filenames expressed as string literals, apply an implementation-specific algorithm to find corresponding files, read the whole contents of each file, and include the results into the library body or program as though wrapped in a top-level begin.

The difference between the two is that include-ci reads each file as if it began with the #!fold-case directive, while include does not. All three may appear at the top level of a program.

Note: Implementations are encouraged to search for files in the directory which contains the including file, and to provide a way for users to specify other directories to search.

Note: For portability, include and include-ci must operate on source files. Their operation on other kinds of files necessarily varies among implementations.

The cond-expand library declaration provides a way to statically expand different library declarations depending on the implementation under which the library is being loaded. A (cond-expand clause) takes the following form:

((feature requirement) (library declaration) ...)

The last clause may be an “else clause,” which has the form

(else (library declaration) ...)

A (feature requirement) takes one of the following forms:

• (feature identifier)
• (library (library name))
• (and (feature requirement) ...)
• (or (feature requirement) ...)
• (not (feature requirement))

Each implementation maintains a list of feature identifiers which are present, as well as a list of libraries which can be imported. The value of a (feature requirement) is determined by replacing each (feature identifier) and (library (library name)) on the implementation’s lists with #t, and all other feature identifiers and library names with #f, then evaluating the resulting expression as a Scheme boolean expression under the normal interpretation of and, or, and not.

A cond-expand is then expanded by evaluating the (feature requirement)s of successive (cond-expand clause)s in order, until one of them returns #t. When a true clause is found, the corresponding (library declaration)s are spliced into the current library definition and the remaining clauses are ignored. If none of the (feature requirement)s evaluate to #t, then if there is an else clause, its (library declaration)s are included. Otherwise, the cond-expand has no effect.

The exact features provided are implementation-defined, but for portability a core set of features is given in appendix B.

After all cond-expand library declarations are expanded, a new environment is constructed for the library consisting of all imported bindings. The expressions and declarations from all begin, include, and include-ci declarations are expanded in that environment in the order in which they occur in the library declaration.

The top-level expressions in a library are executed in the order in which they occur when the library is loaded. A library is loaded zero or more times when it is imported by a program or by another library which is about to be loaded, but must be loaded at least once in every program in which it is so imported.

5.5.2. Library example

The following example shows how a program may be divided into libraries plus a relatively small main program B. If the main program is entered into a REPL, it is not necessary to import the base library.

(define-library (example grid)
  (export make rows cols ref each
            (rename put! set!))
  (import (scheme base))
  (begin
    ;; Create an N x M grid.
    (define (make n m)
      (let ((grid (make-vector n)))
        (do ((i 0 (+ i 1))) ((= i n) grid)
          (vector-set! grid i v)))))
  (define (rows grid)
    (vector-length grid))
  (define (cols grid)
    (vector-length (vector-ref grid 0)))
  (define (ref grid n m)
    (and (< -1 n (rows grid))
         (< -1 m (cols grid))
         (vector-ref (vector-ref grid n) m)))
  (define (put! grid n m v)
    (vector-set! (vector-ref grid n) m v))
  (define (each grid proc)
    (do ((j 0 (+ j 1))) ((= j (rows grid)))
        (do ((k 0 (+ k 1))) ((= k (cols grid))))
            (proc j k))))
6. Standard procedures

This chapter describes Scheme's built-in procedures.

The procedures \texttt{force} and \texttt{eager} are intimately associated with the expression types \texttt{delay} and \texttt{lazy}, and are described with them in section 4.2.5. In the same way, the procedure \texttt{make-parameter} is intimately associated with the expression type \texttt{parameterize}, and is described with it in section 4.2.6.

A program may use a top-level definition to bind any variable. It may subsequently alter any such binding by an assignment (see section 4.1.6). These operations do not modify the behavior of any procedure defined in this report or imported from a library. (see section 5.5). Altering any top-level binding that has not been introduced by a definition has an unspecified effect on the behavior of the procedures defined in this chapter.

6.1. Equivalence predicates

A \texttt{predicate} is a procedure that always returns a boolean value (\#t or \#f). An \texttt{equivalence predicate} is the computational analogue of a mathematical equivalence relation; it is symmetric, reflexive, and transitive. Of the equivalence predicates described in this section, \texttt{eqv?} is the finest or most discriminating, \texttt{equal?} is the coarsest, and \texttt{eqv?} is slightly less discriminating than \texttt{eqv?}.

\begin{verbatim}
(eqv? obj1 obj2)
\end{verbatim}

The \texttt{eqv?} procedure defines a useful equivalence relation on objects. Briefly, it returns \#t if \texttt{obj1} and \texttt{obj2} are normally regarded as the same object. This relation is left slightly open to interpretation, but the following partial specification of \texttt{eqv?} holds for all implementations of Scheme.

The \texttt{eqv?} procedure returns \#t if:

- \texttt{obj1} and \texttt{obj2} are both \#t or both \#f.
- \texttt{obj1} and \texttt{obj2} are both symbols and

\begin{verbatim}
(string=? (symbol->string obj1) (symbol->string obj2))
\end{verbatim}

\texttt{eqv?} procedure

\texttt{Note:} This assumes that neither \texttt{obj1} nor \texttt{obj2} is an “un-interned symbol” as alluded to in section 6.5. This report does not specify the behavior of \texttt{eqv?} on implementation-dependent extensions.
• obj₁ and obj₂ are both numbers, are numerically equal (see =, section 6.2), and are either both exact or both inexact.

• obj₁ and obj₂ are both characters and are the same character according to the char=? procedure (section 3.4).

• obj₁ and obj₂ are both the empty list.

• obj₁ and obj₂ are pairs, vectors, bytectors, records, or strings that denote the same location in the store (section 3.4).

The eqv? procedure returns #f if:

• obj₁ and obj₂ are of different types (section 3.2).

• one of obj₁ and obj₂ is #t but the other is #f.

• obj₁ and obj₂ are symbols but

\[
\begin{align*}
(\text{string=? } (\text{symbol->string } obj₁) \\
(\text{symbol->string } obj₂)) & \implies #f
\end{align*}
\]

• one of obj₁ and obj₂ is an exact number but the other is an inexact number.

• obj₁ and obj₂ are numbers for which the = procedure returns #f, and nan? returns #f for both.

• obj₁ and obj₂ are characters for which the char=? procedure returns #f.

• one of obj₁ and obj₂ is the empty list but the other is not.

• obj₁ and obj₂ are pairs, vectors, bytectors, records, or strings that denote distinct locations.

• obj₁ and obj₂ are procedures that would behave differently (return different values or have different side effects) for some arguments.

\[
\begin{align*}
(\text{eqv? } 'a 'a) & \implies #t \\
(\text{eqv? } 'a 'b) & \implies #f \\
(\text{eqv? } 2 2) & \implies #t \\
(\text{eqv? } '() '()) & \implies #t \\
(\text{eqv? } 100000000 100000000) & \implies #t \\
(\text{eqv? } (\text{cons } 1 2) (\text{cons } 1 2)) & \implies #f \\
(\text{eqv? } (\text{lambda } () 1) \\
(\text{lambda } () 1)) & \implies #f \\
(\text{eqv? } '#f 'nil) & \implies #f \\
(\text{eqv? } '" ") & \implies \text{unspecified} \\
(\text{eqv? } '\#\#() '\#\#()) & \implies \text{unspecified} \\
(\text{eqv? } (\text{lambda } (x) x) \\
(\text{lambda } (x) x)) & \implies \text{unspecified} \\
(\text{let } ((p (\text{lambda } (x) x))) \\
(\text{eqv? } p p)) & \implies \text{unspecified} \\
(\text{eqv? } (\text{lambda } (x) x) \\
(\text{lambda } (y) y)) & \implies \text{unspecified} \\
(\text{eqv? } +\text{nan}.0 +\text{nan}.0) & \implies \text{unspecified}
\end{align*}
\]

The next set of examples shows the use of eqv? with procedures that have local state. The gen-counter procedure must return a distinct procedure every time, since each procedure has its own internal counter. The gen-loser procedure, however, returns equivalent procedures each time, since the local state does not affect the value or side effects of the procedures. However, eqv? may or may not detect this equivalence.

\[
\begin{align*}
(\text{define gen-counter} \\
(\text{lambda } () \\
(\text{let } ((n 0)) \\
(\text{lambda } () (\text{set! } n (+ n 1) n)))) \\
(\text{let } ((g (\text{gen-counter}))) \\
(\text{eqv? } g g)) & \implies #t \\
(\text{eqv? } (\text{gen-counter}) (\text{gen-counter})) & \implies #f
\end{align*}
\]

\[
\begin{align*}
(\text{define gen-loser} \\
(\text{lambda } () \\
(\text{let } ((n 0)) \\
(\text{lambda } () (\text{set! } n (+ n 1) 27)))) \\
(\text{let } ((g (\text{gen-loser}))) \\
(\text{eqv? } g g)) & \implies #t \\
(\text{eqv? } (\text{gen-loser}) (\text{gen-loser})) & \implies \text{unspecified}
\end{align*}
\]

Since it is an error to modify constant objects (those returned by literal expressions), implementations are permitted, though not required, to share structure between constants where appropriate. Thus the value of eqv? on constants is sometimes implementation-dependent.

\[
\begin{align*}
(\text{eqv? } 'a 'a) & \implies \text{unspecified} \\
(\text{eqv? } "a" "a") & \implies \text{unspecified} \\
(\text{eqv? } 'b (\text{cdr } '(a b))) & \implies \text{unspecified} \\
(\text{let } ((x 'a)) \\
(\text{eqv? } x x)) & \implies #t
\end{align*}
\]

Rationale: The above definition of eqv? allows implementations latitude in their treatment of procedures and literals: implementations are free either to detect or to fail to detect that
two procedures or two literals are equivalent to each other, and can decide whether or not to merge representations of equivalent objects by using the same pointer or bit pattern to represent both.

\[(\text{eq? obj1 obj2})\]  

procedure

The \text{eq?} procedure is similar to \text{eqv?} except that in some cases it is capable of discerning distinctions finer than those detectable by \text{eqv?}.

On symbols, booleans, the empty list, pairs, procedures, non-empty strings, vectors, bytevectors, and records, \text{eq?} and \text{eqv?} are guaranteed to have the same behavior. On numbers and characters, \text{eqv?}'s behavior is implementation-dependent, but it will always return either true or false, and will return true only when \text{eqv?} would also return true. On empty strings, vectors, bytevectors, and records, \text{eq?} may also behave differently from \text{eqv?}.

\[
\begin{aligned}
(\text{eq? } 'a 'a) & \implies \#t \\
(\text{eq? } '(a) '(a)) & \implies \text{unspecified} \\
(\text{eq? } (\text{list } 'a) (\text{list } 'a)) & \implies \#f \\
(\text{eq? } "a" "a") & \implies \text{unspecified} \\
(\text{eq? } "" "") & \implies \text{uns pected} \\
(\text{eq? } () () ) & \implies \#t \\
(\text{eq? } 2 2 ) & \implies \text{unspecified} \\
(\text{eq? } #\text{\textbackslash A} #\text{\textbackslash A}) & \implies \text{unspecified} \\
(\text{eq? } \text{car} \text{car}) & \implies \text{unspecified} \\
(\text{let } ((n (+ 2 3))) (\text{eq? } n n)) & \implies \text{uns pected} \\
(\text{let } ((x 'a))) (\text{eq? } x x)) & \implies \#t \\
(\text{let } ((x '#))) (\text{eq? } x x)) & \implies \#t \\
(\text{let } ((p (\text{lambda} (x) x))) (\text{eq? } p p)) & \implies \#t
\end{aligned}
\]

\text{Rationale:} It will usually be possible to implement \text{eq?} much more efficiently than \text{eqv?}, for example, as a simple pointer comparison instead of as some more complicated operation. One reason is that it is not always possible to compute \text{eqv?} of two numbers in constant time, whereas \text{eq?} implemented as pointer comparison will always finish in constant time. In applications using procedures to implement objects with state, \text{eq?} may be used instead of \text{eqv?} since it obeys the same constraints as \text{eqv?}.

\[(\text{equal? obj1 obj2})\]  

procedure

The \text{equal?} procedure recursively compares the contents of pairs, vectors, strings, bytevectors, and records, applying \text{eqv?} on other objects such as numbers and symbols. If two objects are \text{eqv?}, they must be \text{equal?} as well. Even if its arguments are circular data structures, \text{equal?} must always terminate.

\[
\begin{aligned}
(\text{equal? } 'a 'a) & \implies \#t \\
(\text{equal? } '(a) '(a)) & \implies \#t
\end{aligned}
\]

\text{Note:} A rule of thumb is that objects are generally \text{equal?} if they print the same.

### 6.2. Numbers

It is important to distinguish between mathematical numbers, the Scheme numbers that attempt to model them, the machine representations used to implement the Scheme numbers, and notations used to write numbers. This report uses the types \text{number}, \text{complex}, \text{real}, \text{rational}, and \text{integer} to refer to both mathematical numbers and Scheme numbers.

#### 6.2.1. Numerical types

Mathematically, numbers are arranged into a tower of subtypes in which each level is a subset of the level above it:

- \text{number}
- \text{complex number}
- \text{real number}
- \text{rational number}
- \text{integer}

For example, 3 is an integer. Therefore 3 is also a rational, a real, and a complex number. The same is true of the Scheme numbers that model 3. For Scheme numbers, these types are defined by the predicates \text{number?}, \text{complex?}, \text{real?}, \text{rational?}, and \text{integer?}.

There is no simple relationship between a number's type and its representation inside a computer. Although most implementations of Scheme will offer at least two different representations of 3, these different representations denote the same integer.

Scheme's numerical operations treat numbers as abstract data, as independent of their representation as possible. Although an implementation of Scheme may use multiple internal representations of numbers, this should not be apparent to a casual programmer writing simple programs.

It is necessary, however, to distinguish between numbers that are represented exactly and those that might not be. For example, indexes into data structures must be known exactly, as must some polynomial coefficients in a symbolic algebra system. On the other hand, the results of measurements are inherently inexact, and irrational numbers may
be approximated by rational and therefore inexact approximations. In order to catch uses of inexact numbers where exact numbers are required, Scheme explicitly distinguishes exact from inexact numbers. This distinction is orthogonal to the dimension of type.

### 6.2.2. Exactness

Scheme numbers are either exact or inexact. A number is exact if it was written as an exact constant or was derived from exact numbers using only exact operations. A number is inexact if it was written as an inexact constant, if it was derived using inexact ingredients, or if it was derived using inexact operations. Thus inexactness is a contagious property of a number.

If two implementations produce exact results for a computation that did not involve inexact intermediate results, the two ultimate results will be mathematically equivalent. This is generally not true of computations involving inexact numbers since approximate methods such as floating-point arithmetic may be used, but it is the duty of each implementation to make the result as close as practical to the mathematically ideal result.

Rational operations such as + should always produce exact results when given exact arguments. If the operation is unable to produce an exact result, then it may either report the violation of an implementation restriction or it may silently coerce its result to an inexact value. However, (/ 3 4) must not return the mathematically incorrect value 0. See section 6.2.3.

Except for inexact->exact, the operations described in this section must generally return inexact results when given any inexact arguments. An operation may, however, return an exact result if it can prove that the value of the result is unaffected by the inexactness of its arguments. For example, multiplication of any number by an exact zero may produce an exact zero result, even if the other argument is inexact.

### 6.2.3. Implementation restrictions

Implementations of Scheme are not required to implement the whole tower of subtypes given in section 6.2.1 but they must implement a coherent subset consistent with both the purposes of the implementation and the spirit of the Scheme language. For example, implementations in which all numbers are real, or in which non-real numbers are always inexact, or in which exact numbers are always integer, are still quite useful.

Implementations may also support only a limited range of numbers of any type, subject to the requirements of this section. The supported range for exact numbers of any type may be different from the supported range for inexact numbers of that type. For example, an implementation that uses IEEE double-precision floating-point numbers to represent all its inexact real numbers may also support a practically unbounded range of exact integers and rationals while limiting the range of inexact reals (and therefore the range of inexact integers and rationals) to the dynamic range of the IEEE double format. Furthermore, the gaps between the representable inexact integers and rationals are likely to be very large in such an implementation as the limits of this range are approached.

An implementation of Scheme must support exact integers throughout the range of numbers permitted as indexes of lists, vectors, bytevectors, and strings or that result from computing the length of one of these. The length, vector-length, bytector-vector-length, and string-length procedures must return an exact integer, and it is an error to use anything but an exact integer as an index. Furthermore, any integer constant within the index range, if expressed by an exact integer syntax, must be read as an exact integer, regardless of any implementation restrictions that apply outside this range. Finally, the procedures listed below will always return exact integer results provided all their arguments are exact integers and the mathematically expected results are representable as exact integers within the implementation:

```
1 + - *
quotient remainder modulo
max min abs
denominator numerator gcd
floor ceiling
lcm floor ceiling
trunc each/ floor/ ceiling/ centered/
round round/ euclidean/
euclidean/ centered-quotient
floor-quotient floor-remainder
ceiling-quotient ceiling-remainder
truncate-quotient truncate-remainder
round-quotient round-remainder
euclidean-quotient euclidean-remainder
```

It is recommended, but not required, that implementations support exact integers and exact rationals of practically unlimited size and precision, and to implement the above procedures and the / procedure in such a way that they always return exact results when given exact arguments. If one of these procedures is unable to deliver an exact result when given exact arguments, then it may either report a violation of an implementation restriction or it may silently coerce its result to an inexact number; such a coercion can cause an error later. Nevertheless, implementations that do not provide exact rational numbers should return inexact rational numbers rather than reporting an implementation restriction.
An implementation may use floating-point and other approximate representation strategies for inexact numbers. This report recommends, but does not require, that implementations that use floating-point representations follow the IEEE 754 standard, and that implementations using other representations should match or exceed the precision achievable using these floating-point standards [19]. In particular, the description of transcendental functions in IEEE 754-2008 should be followed by such implementations, particularly with respect to infinities and NaNs.

Although Scheme allows a variety of written notations for numbers, any particular implementation may support only some of them. For example, an implementation in which all numbers are real need not support the rectangular and polar notations for complex numbers. If an implementation encounters an exact numerical constant that it cannot represent as an exact number, then it may either report a violation of an implementation restriction or it may silently represent the constant by an inexact number.

6.2.4. Implementation extensions

Implementations may provide more than one representation of floating-point numbers with differing precisions. In an implementation which does so, an inexact result must be represented with at least as much precision as is used to express any of the inexact arguments to that operation. Although it is desirable for potentially inexact operations such as \texttt{sqrt} to produce exact answers when applied to exact arguments, if an exact number is operated upon so as to produce an inexact result, then the most precise representation available must be used. For example, the value of \texttt{(sqrt 4)} should be 2, but in an implementation that provides both single and double precision floating point numbers it may be the latter but must not be the former.

In addition, implementations may distinguish special numbers called positive infinity, negative infinity, NaN, and negative zero. Positive infinity is regarded as an inexact real (but not rational) number that represents an indeterminate value greater than the numbers represented by all rational numbers. Negative infinity is regarded as an inexact real (but not rational) number that represents an indeterminate value less than the numbers represented by all rational numbers.

A NaN is regarded as an inexact real (but not rational) number so indeterminate that it might represent any real value, including positive or negative infinity, and might even be greater than positive infinity or less than negative infinity. It might even represent no number at all, as in the case of \texttt{(asin 2.0)}.

Note that the real and the imaginary parts of a complex number can be infinities or NaNs.

Negative zero is an inexact real value written \texttt{-0.0} which is distinct (in the sense of \texttt{eqv?}) from \texttt{0.0}. A Scheme implementation is not required to distinguish negative zero. If it does, however, the behavior of the transcendental functions is sensitive to the distinction in accordance with IEEE 754. Furthermore, the negation of negative zero is ordinary zero and vice versa. This implies that the sum of two negative zeros is negative, and the result of subtracting (positive) zero from a negative zero is likewise negative. However, numerical comparisons treat negative zero as equal to zero.

6.2.5. Syntax of numerical constants

The syntax of the written representations for numbers is described formally in section [7.1.1]. Note that case is not significant in numerical constants.

A number can be written in binary, octal, decimal, or hexadecimal by the use of a radix prefix. The radix prefixes are \texttt{#b} (binary), \texttt{#o} (octal), \texttt{#d} (decimal), and \texttt{#x} (hexadecimal). With no radix prefix, a number is assumed to be expressed in decimal.

A numerical constant can be specified to be either exact or inexact by a prefix. The prefixes are \texttt{#e} for exact, and \texttt{#i} for inexact. An exactness prefix may appear before or after any radix prefix that is used. If the written representation of a number has no exactness prefix, the constant is inexact if it contains a decimal point or an exponent. Otherwise, it is exact.

In systems with inexact numbers of varying precisions it can be useful to specify the precision of a constant. For this purpose, implementations may accept numerical constants written with an exponent marker that indicates the desired precision of the inexact representation. The letters \texttt{s}, \texttt{f}, \texttt{d}, and \texttt{l}, meaning \texttt{short}, \texttt{single}, \texttt{double}, and \texttt{long} precision respectively, are acceptable in place of \texttt{e}. The default precision has at least as much precision as \texttt{double}, but implementations may allow this default to be set by the user.

\begin{verbatim}
3.14159265358979F0 Round to single — 3.141593
0.6L0 Extend to long — .600000000000000
\end{verbatim}

The numbers positive infinity, negative infinity and NaN are written \texttt{+inf.0}, \texttt{-inf.0} and \texttt{+nan.0} respectively. Implementations are not required to support them, but if they do, they must be in conformance with IEEE 754. However, implementations are not required to support signaling NaNs, or provide a way to distinguish between different NaNs.

6.2.6. Numerical operations

The reader is referred to section [1.3.3] for a summary of the naming conventions used to specify restrictions on the
types of arguments to numerical routines. The examples used in this section assume that any numerical constant written using an exact notation is indeed represented as an exact number. Some examples also assume that certain numerical constants written using an inexact notation can be represented without loss of accuracy; the inexact constants were chosen so that this is likely to be true in implementations that use IEEE doubles to represent inexact numbers.

In general, if a type predicate is true of a number then all higher type predicates are also true of that number. Consequently, if a type predicate is false of a number, then all lower type predicates are also false of that number.

If \( z \) is a complex number, then \((\text{real? } z)\) is true if and only if \((\text{zero? } (\text{imag-part } z))\) and \((\text{exact? } (\text{imag-part } z))\) are both true. If \( x \) is an inexact real number, then \((\text{integer? } x)\) is true if and only if \((= x (\text{round } x))\).

The numbers \( +\text{inf}.0 \), \(-\text{inf}.0 \), and \( +\text{nan}.0 \) are real but not rational.

\[
\begin{align*}
(\text{complex? } 3+4i) & \quad \Rightarrow \ #t \\
(\text{complex? } 3) & \quad \Rightarrow \ #t \\
(\text{real? } -2.5+0i) & \quad \Rightarrow \ #t \\
(\text{real? } -2.5+0.0i) & \quad \Rightarrow \ #f \\
(\text{real? } #e1e10) & \quad \Rightarrow \ #t \\
(\text{real? } +\text{inf}.0) & \quad \Rightarrow \ #t \\
(\text{rational? } -\text{inf}.0) & \quad \Rightarrow \ #f \\
(\text{rational? } 6/10) & \quad \Rightarrow \ #t \\
(\text{rational? } 6/3) & \quad \Rightarrow \ #t \\
(\text{integer? } 3+0i) & \quad \Rightarrow \ #t \\
(\text{integer? } 3.0) & \quad \Rightarrow \ #t \\
(\text{integer? } 8/4) & \quad \Rightarrow \ #t
\end{align*}
\]

Note: The behavior of these type predicates on inexact numbers is unreliable, since any inaccuracy might affect the result.

Note: In many implementations the \text{complex?} procedure will be the same as \text{number?}, but unusual implementations may be able to represent some irrational numbers exactly or may extend the number system to support some kind of non-complex numbers.

\[
\begin{align*}
(\text{exact? } z) & \quad \text{procedure} \\
(\text{inexact? } z) & \quad \text{procedure}
\end{align*}
\]

These numerical predicates provide tests for the exactness of a quantity. For any Scheme number, precisely one of these predicates is true.

\[
\begin{align*}
(\text{exact? } 3.0) & \quad \Rightarrow \ #f \\
(\text{exact? } #e3.0) & \quad \Rightarrow \ #t \\
(\text{inexact? } 3.) & \quad \Rightarrow \ #t
\end{align*}
\]

\[
(\text{exact-integer? } z) 
\]

procedure

Returns \#t if \( z \) is both exact and an integer; otherwise returns \#f.

\[
\begin{align*}
(\text{exact-integer? } 32) & \quad \Rightarrow \ #t \\
(\text{exact-integer? } 32.0) & \quad \Rightarrow \ #f \\
(\text{exact-integer? } 32/5) & \quad \Rightarrow \ #f
\end{align*}
\]

\[
(\text{finite? } z) 
\]

inexact library procedure

The \text{finite?} procedure returns \#t on all real numbers except \(+\text{inf}.0\), \(-\text{inf}.0\), and \(+\text{nan}.0\), and on complex numbers if their real and imaginary parts are both finite. Otherwise it returns \#f.

\[
\begin{align*}
(\text{finite? } 3) & \quad \Rightarrow \ #t \\
(\text{finite? } +\text{inf}.0) & \quad \Rightarrow \ #f \\
(\text{finite? } 3.0+\text{inf}.0i) & \quad \Rightarrow \ #f
\end{align*}
\]

\[
(\text{nan? } z) 
\]

inexact library procedure

The \text{nan?} procedure returns \#t on \(+\text{nan}.0\), and on any complex number if its real part or its imaginary part or both are \(+\text{nan}.0\). Otherwise it returns \#f.

\[
\begin{align*}
(\text{nan? } +\text{nan}.0) & \quad \Rightarrow \ #t \\
(\text{nan? } 32) & \quad \Rightarrow \ #f \\
(\text{nan? } +\text{nan}.0+5.0i) & \quad \Rightarrow \ #t \\
(\text{nan? } 1+2i) & \quad \Rightarrow \ #f
\end{align*}
\]

\[
\begin{align*}
(= z_1 z_2 z_3 \ldots) & \quad \text{procedure} \\
(< x_1 x_2 x_3 \ldots) & \quad \text{procedure} \\
(> x_1 x_2 x_3 \ldots) & \quad \text{procedure} \\
(\leq x_1 x_2 x_3 \ldots) & \quad \text{procedure} \\
(\geq x_1 x_2 x_3 \ldots) & \quad \text{procedure}
\end{align*}
\]

These procedures return \#t if their arguments are (respectively): equal, monotonically increasing, monotonically decreasing, monotonically nondecreasing, or monotonically nonincreasing, and \#f otherwise. If any of the arguments are \(+\text{nan}.0\), all the predicates return \#f.

These predicates are required to be transitive.

Note: The traditional implementations of these predicates in Lisp-like languages are not transitive.

Note: While it is not an error to compare inexact numbers using these predicates, the results are unreliable because a small
inaccuracy can affect the result; this is especially true of = and zero?. When in doubt, consult a numerical analyst.

(zero? z) procedure
(positive? x) procedure
(negative? x) procedure
(odd? n) procedure
(even? n) procedure

These numerical predicates test a number for a particular property, returning #t or #f. See note above.

(max x1 x2 ...) procedure
(min x1 x2 ...) procedure

These procedures return the maximum or minimum of their arguments.

(max 3 4) ⇒ 4 ; exact
(max 3.9 4) ⇒ 4.0 ; inexact

Note: If any argument is inexact, then the result will also be inexact (unless the procedure can prove that the inaccuracy is not large enough to affect the result, which is possible only in unusual implementations). If min or max is used to compare numbers of mixed exactness, and the numerical value of the result cannot be represented as an inexact number without loss of accuracy, then the procedure may report a violation of an implementation restriction.

(+ z1 ...) procedure
(* z1 ...) procedure

These procedures return the sum or product of their arguments.

(+ 3 4) ⇒ 7
(+ 3) ⇒ 3
(+) ⇒ 0
(* 4) ⇒ 4
(*) ⇒ 1

(− z1 z2) procedure
(− z) procedure
(− z1 z2 ...) procedure
(/ z1 z2) procedure
(/ z) procedure
(/ z1 z2 ...) procedure

With two or more arguments, these procedures return the difference or quotient of their arguments, associating to the left. With one argument, however, they return the additive or multiplicative inverse of their argument. It is an error if any argument of / other than the first is an exact zero.

(− 3 4) ⇒ −1
(− 3 4 5) ⇒ −6
(− 3) ⇒ −3
(/ 3 4 5) ⇒ 3/20
(/ 3) ⇒ 1/3

The abs procedure returns the absolute value of its argument.

(abs -7) ⇒ 7
(abs x) procedure

(floor/ n1 n2) procedure
(floor-quotient n1 n2) procedure
(floor-remainder n1 n2) procedure
(ceiling/ n1 n2) procedure
(ceiling-quotient n1 n2) procedure
(ceiling-remainder n1 n2) procedure
(truncate/ n1 n2) procedure
(truncate-quotient n1 n2) procedure
(truncate-remainder n1 n2) procedure
(round/ n1 n2) procedure
(round-quotient n1 n2) procedure
(round-remainder n1 n2) procedure
(euclidean/ n1 n2) procedure
(euclidean-quotient n1 n2) procedure
(euclidean-remainder n1 n2) procedure
(centered/ n1 n2) procedure
(centered-quotient n1 n2) procedure
(centered-remainder n1 n2) procedure

These procedures, all in the division library, implement number-theoretic (integer) division. It is an error if n2 is zero. The procedures ending in / return two integers; the other procedures return an integer. All the procedures compute a quotient nq and remainder nr such that n1 = n2nq + nr. For each of the six division operators, there are three procedures defined as follows:

((operator)/ n1 n2) ⇒ nq nr
((operator)-quotient n1 nq) ⇒ nq
((operator)-remainder n1 n2) ⇒ nr

The remainder nr is determined by the choice of integer nq: nr = n1 − n2nq. Each set of operators uses a different choice of nq:

ceiling nq = [n1/n2]
floor nq = ⌊n1/n2⌋
truncate nq = truncate(n1/n2)
round nq = ⌊n1/n2⌋
euclidean if n2 > 0, nq = [n1/n2]; if n2 < 0, nq = [n1/n2]
centered choose nq such that −n2 ≤ nr ≤ n2

For any of the operators, and for integers n1 and n2 with n2 not equal to 0,

(= n1 (+ (* n2 ((operator)-quotient n1 n2)) ((operator)-remainder n1 n2)))
⇒ #t

provided all numbers involved in that computation are exact.

See [3] for discussion.
(quotient \(n_1 \ n_2\))  procedure
(remainder \(n_1 \ n_2\))  procedure
(modulo \(n_1 \ n_2\))  procedure

The quotient and remainder procedures are equivalent to truncate-quotient and truncate-remainder, respectively, and modulo is equivalent to floor-remainder.

\[
\begin{align*}
\text{(modulo 13 4)} & \Rightarrow 1 \\
\text{(remainder 13 4)} & \Rightarrow 1 \\
\text{(modulo -13 4)} & \Rightarrow 3 \\
\text{(remainder -13 4)} & \Rightarrow -1 \\
\text{(modulo 13 -4)} & \Rightarrow -3 \\
\text{(remainder 13 -4)} & \Rightarrow 1 \\
\text{(modulo -13 -4)} & \Rightarrow -1 \\
\text{(remainder -13 -4)} & \Rightarrow -1 \\
\text{(remainder -13 -4.0)} & \Rightarrow -1.0 \ ; \text{inexact}
\end{align*}
\]

Note: These procedures are provided for backward compatibility with earlier versions of this report.

\[
\begin{align*}
\text{(gcd \(n_1 \ldots\))} & \Rightarrow 4 \\
\text{(gcd)} & \Rightarrow 0 \\
\text{(lcm \(n_1 \ldots\))} & \Rightarrow 288 \\
\text{(lcm 32.0 -36)} & \Rightarrow 288.0 \ ; \text{inexact} \\
\text{(lcm)} & \Rightarrow 1
\end{align*}
\]

\[
\begin{align*}
\text{(rationalize \(x \ y\))} & \Rightarrow 7
\end{align*}
\]

The rationalize procedure returns the simplest rational number differing from \(x\) by no more than \(y\). A rational number \(r_1\) is simpler than another rational number \(r_2\) if \(r_1 = p_1/q_1\) and \(r_2 = p_2/q_2\) (in lowest terms) and \(|p_1| \leq |p_2|\) and \(|q_1| \leq |q_2|\). Thus 3/5 is simpler than 4/7. Although not all rationals are comparable in this ordering (consider 2/7 and 3/5) any interval contains a rational number that is simpler than every other rational number in that interval (the simpler 2/5 lies between 2/7 and 3/5). Note that 0 = 0/1 is the simplest rational of all.

\[
\begin{align*}
\text{(inexact->exact \(\text{rationalize} .3 \ \text{1/10}\))} & \Rightarrow 1/3 \ ; \text{exact} \\
\text{(rationalize .3 \ \text{1/10})} & \Rightarrow \#i1/3 \ ; \text{inexact}
\end{align*}
\]

These procedures compute the usual transcendental functions. The \(\text{log}\) procedure computes the natural logarithm of \(z\) (not the base ten logarithm). The \(\text{asin}\),
acos, and atan procedures compute arcsine \((\sin^{-1})\), arccosine \((\cos^{-1})\), and arctangent \((\tan^{-1})\), respectively. The two-argument variant of atan computes \((\text{angle} (\text{make-rectangular } x \ y))\) (see below), even in implementations that don’t support the complex library.

In general, the mathematical functions log, arcsine, arccosine, and arctangent are multiply defined. The value of \(\log z\) is defined to be the one whose imaginary part lies in the range from \(-\pi\) (exclusive) to \(\pi\) (inclusive). The value of \(\log 0\) is undefined. With \(\log\) defined this way, the values of \(\sin^{-1} z, \cos^{-1} z,\) and \(\tan^{-1} z\) are according to the following formulæ:

\[
\begin{align*}
\sin^{-1} z &= -i \log(iz + \sqrt{1 - z^2}) \\
\cos^{-1} z &= \pi/2 - \sin^{-1} z \\
\tan^{-1} z &= (\log(1 + iz) - \log(1 - iz))/(2i)
\end{align*}
\]

The above specification follows [33], which in turn cites [27]; refer to these sources for more detailed discussion of branch cuts, boundary conditions, and implementation of these functions. When it is possible, these procedures produce a real result from a real argument.

\[
\begin{align*}
\sqrt{z} & \quad \text{inexact library procedure} \\
\text{Returns the principal square root of } z. \text{ The result will have either a positive real part, or a zero real part and a non-negative imaginary part.} \\
\text{(exact-integer-sqrt } k) & \quad \text{procedure} \\
\text{Returns two non-negative exact integers } s \text{ and } r \text{ where } k = s^2 + r \text{ and } k < (s + 1)^2. \\
\text{(exact-integer-sqrt } 4) & \rightarrow 2 \ 0 \\
\text{(exact-integer-sqrt } 5) & \rightarrow 2 \ 1 \\
\text{expt } z_1 \ z_2 & \quad \text{procedure} \\
\text{Returns } z_1 \text{ raised to the power } z_2. \text{ For nonzero } z_1, \text{ this is } z_1^{z_2} = e^{z_2 \log z_1}. \\
0.0^z & \text{ is } 1.0 \text{ if } z = 0.0, \text{ and } 0.0 \text{ if } (\text{real-part } z) \text{ is positive.} \\
\text{For other cases in which the first argument is zero, either an error is signalled or an unspecified number is returned.} \\
\text{(make-rectangular } x_1 \ x_2) & \quad \text{complex library procedure} \\
\text{(make-polar } x_3 \ x_4) & \quad \text{complex library procedure} \\
\text{(real-part } z) & \quad \text{complex library procedure} \\
\text{(imag-part } z) & \quad \text{complex library procedure} \\
\text{(magnitude } z) & \quad \text{complex library procedure} \\
\text{(angle } z) & \quad \text{complex library procedure}
\end{align*}
\]

Let \(x_1, x_2, x_3, \) and \(x_4\) be real numbers and \(z\) be a complex number such that

\[z = x_1 + x_2i = x_3 \cdot e^{ix_4}\]

Then all of

\[
\begin{align*}
\text{(make-rectangular } x_1 \ x_2) & \rightarrow z \\
\text{(make-polar } x_3 \ x_4) & \rightarrow z \\
\text{(real-part } z) & \rightarrow x_1 \\
\text{(imag-part } z) & \rightarrow x_2 \\
\text{(magnitude } z) & \rightarrow |x_3| \\
\text{(angle } z) & \rightarrow x_{angle}
\end{align*}
\]

are true, where \(-\pi < x_{angle} \leq \pi\) with \(x_{angle} = x_4 + 2\pi n\) for some integer \(n\).

The make-polar procedure may return an inexact complex number even if its arguments are exact.

\textit{Rationale:} The magnitude procedure is the same as abs for a real argument, but abs is in the base library, whereas magnitude is in the optional complex library.

\[
\begin{align*}
\text{(exact->inexact } z) & \quad \text{procedure} \\
\text{(inexact->exact } z) & \quad \text{procedure}
\end{align*}
\]

The procedure exact->inexact returns an inexact representation of \(z\). The value returned is the inexact number that is numerically closest to the argument. For inexact arguments, the result is the same as the argument. For exact complex numbers, the result is a complex number whose real and imaginary parts are the result of applying exact->inexact to the real and imaginary parts of the argument, respectively. If an exact argument has no reasonably close inexact equivalent, then a violation of an implementation restriction may be reported.

The procedure inexact->exact returns an exact representation of \(z\). The value returned is the exact number that is numerically closest to the argument. For exact arguments, the result is the same as the argument. For inexact non-integer real arguments, the implementation may return a rational approximation, or may report an implementation violation. For inexact complex arguments, the result is a complex number whose real and imaginary parts are the result of applying inexact->exact to the real and imaginary parts of the argument, respectively. If an inexact argument has no reasonably close exact equivalent, then a violation of an implementation restriction may be reported.

These procedures implement the natural one-to-one correspondence between exact and inexact integers throughout an implementation-dependent range. See section 6.2.3.
6.2.7. Numerical input and output

\[(\text{number->string } z)\] procedure
\[(\text{number->string } z \text{ radix})\] procedure

It is an error if \(\text{radix}\) is not one of 2, 8, 10, or 16. If omitted, \(\text{radix}\) defaults to 10. The procedure \text{number->string} takes a number and a radix and returns as a string an external representation of the given number in the given radix such that

\[
(\text{let } ((\text{number number})
(\text{radix radix})
(\text{eqv? number}
(\text{string->number (string->number string radix)}
\text{radix)))))
\]

is true. It is an error if no possible result makes this expression true.

If \(z\) is inexact, the radix is 10, and the above expression can be satisfied by a result that contains a decimal point, then the result contains a decimal point and is expressed using the minimum number of digits (exclusive of exponent and trailing zeroes) needed to make the above expression true \[\text{[7, 9]}\]; otherwise the format of the result is unspecified.

The result returned by \text{number->string} never contains an explicit radix prefix.

\text{Note}: The error case can occur only when \(z\) is not a complex number or is a complex number with a non-rational real or imaginary part.

\text{Rationale}: If \(z\) is an inexact number and the radix is 10, then the above expression is normally satisfied by a result containing a decimal point. The unspecified case allows for infinities, NaNs, and unusual representations.

\[(\text{string->number } string)\] procedure
\[(\text{string->number } string \text{ radix})\] procedure

Returns a number of the maximally precise representation expressed by the given \text{string}. It is an error if \text{radix} is not 2, 8, 10, or 16. If supplied, \text{radix} is a default radix that will be overridden if an explicit radix prefix is present in \text{string} (e.g. "#o177"). If \text{radix} is not supplied, then the default radix is 10. If \text{string} is not a syntactically valid notation for a number, then \text{string->number} returns \#f.

\[
(\text{string->number "100"}) \implies 100
(\text{string->number "100" 16}) \implies 256
(\text{string->number "1e2"}) \implies 100.0
\]

\text{Note}: The domain of \text{string->number} may be restricted by implementations in the following ways. Whenever \text{string} contains an explicit radix prefix, \text{string->number} is permitted to return \#f. If all numbers supported by an implementation are

6.3. Booleans

The standard boolean objects for true and false are written as \#t and \#f. Alternatively, they may be written \#true and \#false, respectively. What really matters, though, are the objects that the Scheme conditional expressions (if, cond, and, or, when, unless, do) treat as true or false. The phrase “a true value” (or sometimes just “true”) means any object treated as true by the conditional expressions, and the phrase “a false value” (or “false”) means any object treated as false by the conditional expressions.

Of all the Scheme values, only \#f counts as false in conditional expressions. All other Scheme values, including \#t, count as true.

\text{Note}: Unlike some other dialects of Lisp, Scheme distinguishes \#f and the empty list from each other and from the symbol nil.

Boolean constants evaluate to themselves, so they do not need to be quoted in programs.

\[(\not \text{obj})\] procedure

The \not procedure returns \#t if \text{obj} is false, and returns \#f otherwise.

\[(\text{boolean? } \text{obj})\] procedure

The \text{boolean?} predicate returns \#t if \text{obj} is either \#t or \#f and returns \#f otherwise.
6.4. Pairs and lists

A pair (sometimes called a dotted pair) is a record structure with two fields called the car and cdr fields (for historical reasons). Pairs are created by the procedure cons. The car and cdr fields are accessed by the procedures car and cdr. The car and cdr fields are assigned by the procedures set-car! and set-cdr!.

Pairs are used primarily to represent lists. A list can be defined recursively as either the empty list or a pair whose cdr is a list. More precisely, the set of lists is defined as the smallest set \( X \) such that

- The empty list is in \( X \).
- If list is in \( X \), then any pair whose cdr field contains list is also in \( X \).

The objects in the car fields of successive pairs of a list are the elements of the list. For example, a two-element list is a pair whose car is the first element and whose cdr is a pair whose car is the second element and whose cdr is the empty list. The length of a list is the number of elements, which is the same as the number of pairs.

The empty list is a special object of its own type. It is not a pair, it has no elements, and its length is zero.

Note: The above definitions imply that all lists have finite length and are terminated by the empty list.

The most general notation (external representation) for Scheme pairs is the “dotted” notation \((c_1 . c_2)\) where \(c_1\) is the value of the car field and \(c_2\) is the value of the cdr field. For example \((4 . 5)\) is a pair whose car is 4 and whose cdr is 5. Note that \((4 . 5)\) is the external representation of a pair, not an expression that evaluates to a pair.

A more streamlined notation can be used for lists: the elements of the list are simply enclosed in parentheses and separated by spaces. The empty list is written \(()\). For example,

\[
(a \ b \ c \ d \ e)
\]

and

\[
(a . (b . (c . (d . (e . ()))))
\]

are equivalent notations for a list of symbols.

A chain of pairs not ending in the empty list is called an improper list. Note that an improper list is not a list. The list and dotted notations can be combined to represent improper lists:

\[
(a \ b \ c . d)
\]

is equivalent to

\[(a . (b . (c . d)))\]

Whether a given pair is a list depends upon what is stored in the cdr field. When the set-cdr! procedure is used, an object can be a list one moment and not the next:

\[
\begin{align*}
\text{(define } x \text{ (list } 'a \ 'b \ 'c) \text{)} \\
\text{(define } y \text{ x) } \Rightarrow (a \ b \ c) \\
\text{(list? y) } \Rightarrow \#t \\
\text{(set-cdr! x 4) } \Rightarrow \text{ unspecified} \\
x & \Rightarrow (a . 4) \\
\text{(eqv? x y) } \Rightarrow \#t \\
y & \Rightarrow (a . 4) \\
\text{(list? y) } \Rightarrow \#f \\
\text{(set-cdr! x x) } \Rightarrow \text{ unspecified} \\
\text{(list? x) } \Rightarrow \#f
\end{align*}
\]

Within literal expressions and representations of objects read by the read procedure, the forms \( '('\)datum\), \( '\langle\)datum\), \( ',\langle\)datum\), and \( ',\langle\)datum\) denote two-element lists whose first elements are the symbols quote, quasiquote, unquote, and unquote-splicing, respectively. The second element in each case is \(\langle\)datum\). This convention is supported so that arbitrary Scheme programs can be represented as lists. That is, according to Scheme’s grammar, every \(\langle\)expression\) is also a \(\langle\)datum\) (see section 7.1.2). Among other things, this permits the use of the read procedure to parse Scheme programs. See section 3.3.

\[
\text{(pair? obj) } \quad \text{procedure}
\]

The pair? predicate returns \#t if obj is a pair, and otherwise returns \#f.

\[
\begin{align*}
\text{(pair? '('a . b)) } & \Rightarrow \#t \\
\text{(pair? '(a b c)) } & \Rightarrow \#t \\
\text{(pair? '()) } & \Rightarrow \#f \\
\text{(pair? '#(a b)) } & \Rightarrow \#f
\end{align*}
\]

\[
\text{(cons obj}_1 \text{ obj}_2) \quad \text{procedure}
\]

Returns a newly allocated pair whose car is \(\text{obj}_1\) and whose cdr is \(\text{obj}_2\). The pair is guaranteed to be different (in the sense of eqv?) from every existing object.

\[
\begin{align*}
\text{(cons 'a '()) } & \Rightarrow (a) \\
\text{(cons '(a) '(b c d)) } & \Rightarrow ((a) \ b \ c \ d) \\
\text{(cons "a" '(b c)) } & \Rightarrow ("a" \ b \ c) \\
\text{(cons 'a '3) } & \Rightarrow (a . 3) \\
\text{(cons '(a b) 'c) } & \Rightarrow ((a \ b) . c)
\end{align*}
\]

\[
\text{(car pair) } \quad \text{procedure}
\]

Returns the contents of the car field of pair. Note that it is an error to take the car of the empty list.
(car '(a b c)) => a
(car '((a) b c d)) => (a)
(car '(1 . 2)) => 1
(car '()) => error

(cdr pair) procedure
Returns the contents of the cdr field of pair. Note that it is an error to take the cdr of the empty list.
(cdr '((a) b c d)) => (b c d)
(cdr '(1 . 2)) => 2
(cdr '()) => error

(set-car! pair obj) procedure
Stores obj in the car field of pair. The value returned by set-car! is unspecified.

(define (f) (list 'not-a-constant-list))
(define (g) '(constant-list))
(set-car! (f) 3) => unspecified
(set-car! (g) 3) => error

(set-cdr! pair obj) procedure
Stores obj in the cdr field of pair. The value returned by set-cdr! is unspecified.

(make-list k) procedure
Returns a newly allocated list of k elements. If a second argument is given, then each element is initialized to fill. Otherwise the initial contents of each element is unspecified.

(make-list 2 3) => (3 3)

(list obj ...) procedure
Returns a newly allocated list of its arguments.
(list 'a (+ 3 4) 'c) => (a 7 c)
(list) => ()

(length list) procedure
Returns the length of list.
(length '(a b c)) => 3
(length '((a) b (c d e))) => 3
(length '()) => 0

(append list ...) procedure
Returns a list consisting of the elements of the first list followed by the elements of the other lists.
(append '(x) '(y)) => (x y)
(append '(a) '(b c d)) => (a b c d)
(append '(a (b)) '((c))) => (a (b) (c))

The resulting list is always newly allocated, except that it shares structure with the last list argument. The last argument may actually be any object; an improper list results if the last argument is not a proper list.

(reverse list) procedure
Returns a newly allocated list consisting of the elements of list in reverse order.
(reverse '(a b c)) => (c b a)
(reverse '(a (b c) d (e (f)))) => ((e (f)) d (b c) a)

(list-tail list k) procedure
Returns the sublist of list obtained by omitting the first k elements. It is an error if list has fewer than k elements. The list-tail procedure could be defined by
(define list-tail
  (lambda (x k)
    (if (zero? k)
        x
        (list-tail (cdr x) (- k 1)))))

(list-ref list k) procedure

Returns the kth element of list. (This is the same as the car of (list-tail list k).) It is an error if list has fewer than k elements.

(list-ref '((a b c d) 2)) ⇒ c
(list-ref '((a b c d)
          (inexact->exact (round 1.8)))
    ) ⇒ c

(list-set! list k obj) procedure

The list-set! procedure stores obj in element k of list. It is an error if k is not a valid index of list. The value returned by list-set! is unspecified.

(list-set! (ls (list 'one 'two 'five!))
          ls 2 'three)
⇒ (one two three)

Rationale: Although they are often used as predicates, memq, memv, member, assq, assv, and assoc do not have question marks in their names because they return potentially useful values rather than just #t or #f.

(list-copy list) procedure

Returns a newly allocated copy of the given list. Only the pairs themselves are copied; the cars of the result are the same (in the sense of eqv?) as the cars of list. If the last pair of list has a cdr which is not the empty list, the last pair of the result does, too. An argument which is not a list is returned unchanged.

6.5. Symbols

Symbols are objects whose usefulness rests on the fact that two symbols are identical (in the sense of eqv?) if and only if their names are spelled the same way. For instance, they can be used the way enumerated values are used in other languages. The rules for writing a symbol are exactly the same as the rules for writing an identifier; see sections 2.1 and 7.1.1.

It is guaranteed that any symbol that has been returned as part of a literal expression, or read using the read procedure, and subsequently written out using the write procedure, will read back in as the identical symbol (in the sense of eqv?).

(define e '((a 1) (b 2) (c 3)))
(assoc 'a e) ⇒ (a 1)
(assoc 'b e) ⇒ (b 2)
(assoc 'c e) ⇒ #f
(assoc (list 'a) '(((a)) ((b)) ((c)))) ⇒ #f
(assoc (list 'a) '((a)) ((b)) ((c))))⇒ #f
(assoc 2.0 '(((1 1) (2 4) (3 9)) =)⇒ (2 4)
(assoc 5 '((2 3) (5 7) (11 13)))⇒ unspecified
(assv 5 '((2 3) (5 7) (11 13)))⇒ (5 7)
Note: Some implementations have values known as “uninterned symbols,” which defeat write/read invariance, and also violate the rule that two symbols are the same if and only if their names are spelled the same.

(symbol? obj) procedure
Returns #t if obj is a symbol, otherwise returns #f.

(symbol? 'foo) ⇒ #t
(symbol? (car '(a b))) ⇒ #t
(symbol? "bar") ⇒ #f
(symbol? 'nil) ⇒ #t
(symbol? '()) ⇒ #f
(symbol? #f) ⇒ #f

(symbol->string symbol) procedure
Returns the name of symbol as a string. It is an error to apply mutation procedures like string-set! to strings returned by this procedure.

(symbol->string 'flying-fish) ⇒ "flying-fish"
(symbol->string 'Martin) ⇒ "Martin"
(symbol->string (string->symbol "Malvina")) ⇒ "Malvina"

(string->symbol string) procedure
Returns the symbol whose name is string. This procedure can create symbols with names containing special characters that would require escaping when written.

(string->symbol "mISSISSIppi") ⇒ mISSISSIppi
(eq? 'bitBlt (string->symbol "bitBlt")) ⇒ #t
(eq? 'JollyWog (string->symbol 'JollyWog)) ⇒ #t
(string=? "K. Harper, M.D." (symbol->string (string->symbol "K. Harper, M.D."))) ⇒ #t

6.6. Characters

Characters are objects that represent printed characters such as letters and digits. All Scheme implementations must support at least the ASCII character repertoire: that is, Unicode characters U+0000 through U+007F. Implementations may support any other Unicode characters they see fit, and may also support non-Unicode characters as well. Except as otherwise specified, the result of applying any of the following procedures to a non-Unicode character is implementation-dependent.

Characters are written using the notation #\(character) or #\(character name) or #\x{hex scalar value}.

Here are some examples:

#\a ; lower case letter
#\A ; upper case letter
#\( ; left parenthesis
#\ ; the space character
#\iota ; i (if supported)
#\x03BB ; λ (if supported)

The following character names must be supported by all implementations:

#\alarm ; U+0007
#\backspace ; U+0008
#\delete ; U+007F
#\escape ; U+001B
#\newline ; the linefeed character, U+000A
#\null ; the null character, U+0000
#\return ; the return character, U+000D
#\space ; the preferred way to write a space
#\tab ; the tab character, U+0009

Case is significant in #\(character), and in #\(character name), but not in #\x{hex scalar value}. If (character) in #\(character) is alphabetic, then any character immediately following (character) must be a delimiter character such as a space or parenthesis. This rule resolves the ambiguous case where, for example, the sequence of characters “#\space” could be taken to be either a representation of the space character or a representation of the character “#\s” followed by a representation of the symbol “pace.”

Characters written in the #\ notation are self-evaluating. That is, they do not have to be quoted in programs.

Some of the procedures that operate on characters ignore the difference between upper case and lower case. The procedures that ignore case have “-ci” (for “case insensitive”) embedded in their names.

(char? obj) procedure
Returns #t if obj is a character, otherwise returns #f.
These procedures return #t if the Unicode codepoints corresponding to their arguments are (respectively): equal, monotonically increasing, monotonically decreasing, monotonically nondecreasing, or monotonically nonincreasing.

These predicates are required to be transitive.

These procedures impose a total ordering on the set of characters which is the same as the Unicode code point ordering. This is true whether or not the implementation uses the Unicode representation internally.

(char-ci=? char1 char2 char3 ...)  
(char-ci<? char1 char2 char3 ...)  
(char-ci>? char1 char2 char3 ...)  
(char-ci<=? char1 char2 char3 ...)  
(char-ci=>? char1 char2 char3 ...)  

These procedures are similar to char=? et cetera, but they treat upper case and lower case letters as the same. For example, (char-ci=? #\A #\a) returns #t.

Specifically, these procedures behave as if char-foldcase were applied to their arguments before they were compared.

(char-alphabetic? char)  
(char-numeric? char)  
(char-whitespace? char)  
(char-upper-case? letter)  
(char-lower-case? letter)  

These procedures return #t if their arguments are alphabetic, numeric, whitespace, upper case, or lower case characters, respectively, otherwise they return #f.

Specifically, they must return #t when applied to characters with the Unicode properties Alphabetic, Numeric_Digit, White_Space, Uppercase, and Lowercase respectively, and #f when applied to any other Unicode characters. Note that many Unicode characters are alphabetic but neither upper nor lower case.

(digit-value char)  

This procedure returns the numeric value (0 to 9) of its argument if it is a numeric digit (that is, if char-numeric? returns #t), or #f on any other character.

<table>
<thead>
<tr>
<th>digit-value</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>#\3</td>
<td>3</td>
</tr>
<tr>
<td>#\x0664</td>
<td>4</td>
</tr>
<tr>
<td>#\x0EA6</td>
<td>0</td>
</tr>
</tbody>
</table>

Given a Unicode character, char->integer returns an exact integer between 0 and #xD7FF or between #xE000 and #x10FFFF which is equal to the Unicode code point of that character. Given a non-Unicode character, it returns an exact integer greater than #x10FFFF. This is true independent of whether the implementation uses the Unicode representation internally.

Given an exact integer that is the value returned by a character when char->integer is applied to it, integer->char returns that character.

(char-upcase char)  
(char-downcase char)  
(char-foldcase char)  

The char-upcase procedure, given an argument that is the lowercase part of a Unicode casing pair, returns the uppercase member of the pair, provided that both characters are supported by the Scheme implementation. Note that language-sensitive casing pairs are not used. If the argument is not the lowercase member of such a pair, it is returned.

The char-downcase procedure, given an argument that is the uppercase part of a Unicode casing pair, returns the lowercase member of the pair, provided that both characters are supported by the Scheme implementation. Note that language-sensitive casing pairs are not used. If the argument is not the uppercase member of such a pair, it is returned.

The char-foldcase procedure applies the Unicode simple case-folding algorithm to its argument and returns the result. Note that language-sensitive folding is not used. If the argument is an uppercase letter, the result will be either a lowercase letter or the same as the argument if the lowercase letter does not exist or is not supported by the implementation. See UAX #29 [14] (part of the Unicode Standard) for details.

Note that many Unicode lowercase characters do not have uppercase equivalents.

6.7. Strings

Strings are sequences of characters. Strings are written as sequences of characters enclosed within double quotes (").

Within a string literal, various escape sequences represent characters other than themselves. Escape sequences always start with a backslash (\):

- \a : alarm, U+0007
- \b : backspace, U+0008
make-string

strings. It is an error to pass such a forbidden character to
acters U+0000 to U+00FF (the Latin-1 repertoire) in
strings. It is an error to pass such a forbidden character to

Implementations may forbid certain characters from ap-

in their names.

ignore case have “-ci” embedded in their names.

Implementations may forbid certain characters from ap-
ppearing in strings. For example, an implementation might
support the entire Unicode repertoire, but only allow char-
acters U+0000 to U+00FF (the Latin-1 repertoire) in
strings. It is an error to pass such a forbidden character to
make-string, string, string-set!, or string-fill!.

The result is unspecified if any other character in a string
occurs after a backslash.

Except for a line ending, any character outside of an escape
sequence stands for itself in the string literal. A line end-
ing which is preceded by \(\text{\textbackslash}{\text{intraline whitespace}}\) expands
to nothing (along with any trailing intraline whitespace),
and can be used to indent strings for improved legibility.
Any other line ending has the same effect as inserting a \n
character into the string.

Examples:

"The word "\text{\textbackslash}recursion\" has many meanings."
"Another example:\ntwo lines of text"
"Here's a text \n  containing just one line"
\x03B1; is named GREEK SMALL LETTER ALPHA."

The length of a string is the number of characters that it
contains. This number is an exact, non-negative integer
that is fixed when the string is created. The valid indexes
of a string are the exact non-negative integers less than
the length of the string. The first character of a string has
index 0, the second has index 1, and so on.

In phrases such as “the characters of string beginning with
index start and ending with index end,” it is understood
that the index start is inclusive and the index end is ex-
clusive. Thus if start and end are the same index, a null
substring is referred to, and if start is zero and end is the
length of string, then the entire string is referred to. It is
an error if start is less than end.

Some of the procedures that operate on strings ignore the
difference between upper and lower case. The versions that
ignore case have “-ci” (for “case insensitive”) embedded
in their names.

(string? obj) procedure
Returns \#t if obj is a string, otherwise returns \#f.

(make-string k) procedure
(make-string k char) procedure
The make-string procedure returns a newly allocated
string of length k. If char is given, then all the characters
of the string are initialized to char, otherwise the contents
of the string are unspecified.

(string char ...) procedure
Returns a newly allocated string composed of the arguments. It is analogous to list.

(string-length string) procedure
Returns the number of characters in the given string.

(string-ref string k) procedure
It is an error if k is not a valid index of string. The
string-ref procedure returns character k of string using
zero-origin indexing. There is no requirement for this
procedure to execute in constant time.

(string-set! string k char) procedure
It is an error if k is not a valid index of string. The
string-set! procedure stores char in element k of string
and returns an unspecified value. There is no requirement
for this procedure to execute in constant time.

(string=? string1 string2 string3 ...) procedure
Returns \#t if all the strings are the same length and contain
exactly the same characters in the same positions, other-
wise returns \#f.

(string-ci=? string1 string2 string3 ...) string library procedure
Returns \#t if, after case-folding, all the strings are the
same length and contain the same characters in the same
positions, otherwise returns \#f. Specifically, these proce-
dures behave as if string-foldcase were applied to their
arguments before comparing them.
(string-ni=? string₁ string₂ string₃ ...) procedure
Returns #t if, after an implementation-defined normalization, all the strings are the same length and contain the same characters in the same positions, otherwise returns #f. The intent is to provide a means of comparing strings that are considered equivalent in some situations but are represented by a different sequence of characters.

Specifically, an implementation which supports Unicode should use either Unicode normalization NFC or NFD as specified by Unicode UAX#15 [13]. Implementations which only support ASCII or some other character set which provides no ambiguous representations of character sequences may define the normalization to be the identity operation, in which case string-ni=? is equivalent to string=?.

(string<? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ci<? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ni<? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string>? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ci>? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ni>? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string<=? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ci<=? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ni<=? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string>? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ci>? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ni>? string₁ string₂ string₃ ...) procedure
(char library procedure)
(string-ni<=? string₁ string₂ string₃ ...) procedure
(char library procedure)

These procedures return #t if their arguments are (respectively): equal, monotonically increasing, monotonically decreasing, monotonically nondecreasing, or monotonically nonincreasing.

These predicates are required to be transitive. These procedures compare strings in an implementation-defined way. One approach is to make them the lexicographic extensions to strings of the corresponding orderings on characters. In that case, string<? would be the lexicographic ordering on strings induced by the ordering char<? on characters, and if the two strings differ in length but are the same up to the length of the shorter string, the shorter string would be considered to be lexicographically less than the longer string. However, it is also permitted to use the natural ordering imposed by the internal representation of strings, or a more complex locale-specific ordering.

In all cases, a pair of strings must satisfy exactly one of string<?, string=? , and string>? , and must satisfy string<? if and only if they do not satisfy string>? and string=? if and only if they do not satisfy string<?.

The “ci” procedures behave as if they applied string-foldcase to their arguments before invoking the corresponding procedures without “-ci”.

The “ni” procedures behave as if they applied the implementation-defined normalization used by string-ni=? to their arguments before invoking the corresponding procedures without “-ni”.

(string-upcase string) char library procedure
(string-downcase string) char library procedure
(string-foldcase string) char library procedure

These procedures apply the Unicode full string uppercasing, lowercasing, and case-folding algorithms to their arguments and return the result. If the result is equal to the argument, the argument may be returned. Note that language-sensitive mappings and foldings are not used. The result may differ in length from the argument. What is more, a few characters have case-mappings that depend on the surrounding context. For example, Greek capital sigma normally lowers cases to Greek small sigma, but at the end of a word it downcases to Greek small final sigma instead. See UAX #29 [14] (part of the Unicode Standard) for details.

(substring string start end) procedure
It is an error if start and end are not exact integers satisfying the inequality

\[ 0 \leq \text{start} \leq \text{end} \leq (\text{string-length string}). \]

The substring procedure returns a newly allocated string formed from the characters of string beginning with index start (inclusive) and ending with index end (exclusive).

(string-append string ...) procedure
Returns a newly allocated string whose characters are the concatenation of the characters in the given strings.

(string->list string) procedure
(list->string list) procedure
string->list returns a newly allocated list of the characters that make up the given string. list->string returns a newly allocated string formed from the elements in the list list. It is an error if any element is not a character. In both procedures, order is preserved. string->list and list->string are inverses so far as equal? is concerned.
(string-copy string) procedure
Returns a newly allocated copy of the given string.

(string-fill! string char) procedure
(string-fill! string char start end) procedure
If start and end are given, string-fill! stores fill in all the elements of string between start (inclusive) and end (exclusive). It is an error if fill is not a character or is forbidden in strings, or if start is less than end. If start and endy are omitted, fill is stored in all the elements of string. In any case, an unspecified value is returned.

6.8. Vectors
Vectors are heterogeneous structures whose elements are indexed by integers. A vector typically occupies less space than a list of the same length, and the average time needed to access a randomly chosen element is typically less for the vector than for the list.

The length of a vector is the number of elements that it contains. This number is a non-negative integer that is fixed when the vector is created. The valid indexes of a vector are the exact non-negative integers less than the length of the vector. The first element in a vector is indexed by zero, and the last element is indexed by one less than the length of the vector.

Vectors are written using the notation #(obj ...). For example, a vector of length 3 containing the number zero in element 0, the list (2 2 2 2) in element 1, and the string "Anna" in element 2 can be written as following:

#(0 (2 2 2 2) "Anna")

Note that this is the external representation of a vector, not an expression evaluating to a vector. It is an error not to quote a vector constant:

' #(0 (2 2 2 2) "Anna")

(vector 'a 'b 'c) ⇒ #(a b c)

(vector-length vector) procedure
Returns the number of elements in vector as an exact integer.

(vector-ref vector k) procedure
It is an error if k is not a valid index of vector. The vector-ref procedure returns the contents of element k of vector.

(vector-ref #{1 1 2 3 5 8 13 21} 5) ⇒ 8
(vector-ref #{1 1 2 3 5 8 13 21} (inexact->exact (round (* 2 (acos -1)))))) ⇒ 13

(vector-set! vector k obj) procedure
It is an error if k is not a valid index of vector. The vector-set! procedure stores obj in element k of vector. The value returned by vector-set! is unspecified.

(let ((vec (vector 0 '(2 2 2 2) "Anna")))
 (vector-set! vec 1 ,("Sue" "Sue"))
 vec) ⇒ #(0 ,("Sue" "Sue") "Anna")

(vector-set! #{0 1 2} 1 "doe") ⇒ error ; constant vector

(vector->list vector) procedure
(list->vector list) procedure
The vector->list procedure returns a newly allocated list of the objects contained in the elements of vector. The list->vector procedure returns a newly created vector initialized to the elements of the list list. In both procedures, order is preserved.

(vector->list #{dah dah didah}) ⇒ (dah dah didah)
(list->vector ,"dididit dah") ⇒ #,("dididit dah")

(vector->string string) procedure
(string->vector vector) procedure
The vector->string procedure returns a newly allocated string of the objects contained in the elements of vector. It is an error if any element is not a character allowed in strings. The string->vector procedure returns a newly created vector initialized to the elements of the string string. In both procedures, order is preserved.
Returns a newly allocated copy of the given vector. The elements of the new vector are the same (in the sense of eqv?) as the elements of the old.

The arguments start, end, and fill default to 0, the length of vector, and an implementation-specified value respectively. If end is greater than the length of vector, the fill argument is used to fill the additional elements of the result.

If start and end are given, vector-fill! stores fill (which can be any object) in all the elements of vector between start (inclusive) and end (exclusive). It is an error if start is less than end. If they are omitted, fill is stored in all the elements of vector. In either case, an unspecified value is returned.

**6.9. Bytevectors**

Bytevectors represent blocks of binary data. They are fixed-length sequences of bytes, where a byte is an exact integer in the range [0, 255]. A bytevector is typically more space-efficient than a vector containing the same values.

The length of a bytevector is the number of elements that it contains. This number is a non-negative integer that is fixed when the bytevector is created. The valid indexes of a bytevector are the exact non-negative integers less than the length of the bytevector, starting at index zero as with vectors.

Bytevectors are written using the notation #\u8(byte ...). For example, a bytevector of length 3 containing the byte 0 in element 0, the byte 10 in element 1, and the byte 5 in element 2 can be written as following:

#\u8(0 10 5)

Note that this is both the external representation of a bytevector and an expression evaluating to a bytevector.

Returns #t if obj is a bytevector. Otherwise, #f is returned.

The make-bytevector procedure returns a newly allocated bytevector of length k. If byte is given, then all elements of the bytevector are initialized to byte, otherwise the contents of each element are unspecified.

Returns the length of bytevector in bytes as an exact integer.

Returns the kth byte of bytevector.

Stores byte as the kth byte of bytevector. The value returned by bytevector-u8-set! is unspecified.

Returns a newly allocated bytevector containing the same bytes as bytevector.

Copies the bytes of bytevector from to bytevector to. It is an error if to is shorter than from. The value returned by bytevector-copy! is unspecified.

Returns a newly allocated bytevector containing the bytes in bytevector between start (inclusive) and end (exclusive). It is an error if start is less than end, or start is less than zero, or end is greater than the length of bytevector.

Copies the bytes of bytevector from between start and end to bytevector to, starting at at. The order in which bytes are copied is unspecified, except that if the source and destination overlap, copying takes place as if the source is first copied into a temporary bytevector and then into the destination. This can be achieved without allocating storage by making sure to copy in the correct direction in such circumstances.

It is an error if start is less than end, or start is less than zero, or end is greater than the length of from, or to is less than zero or greater than the length of to. It is also an error if the inequality (>= (- (bytevector-length...
6. Standard procedures

(\text{utf8}\rightarrow\text{string} \ \text{bytevector}) \quad \text{procedure}

(\text{string}\rightarrow\text{utf8} \ \text{string}) \quad \text{procedure}

These procedures translate between strings and bytevectors that encode those strings using the UTF-8 encoding. The \text{utf8}\rightarrow\text{string} procedure decodes a bytevector and returns the corresponding string; the \text{string}\rightarrow\text{utf8} procedure encodes a string and returns the corresponding bytevector. It is an error to pass invalid byte sequences or byte sequences representing characters which are forbidden in strings to \text{utf8}\rightarrow\text{string}.

\begin{align*}
(\text{utf8}\rightarrow\text{string} \ \text{#u8}(\text{#x41})) & \Rightarrow \text{"A"} \\
(\text{string}\rightarrow\text{utf8} \ \text{"λ"}) & \Rightarrow \text{#u8}(\text{#xCE} \ \text{#xBB})
\end{align*}

6.10. Control features

This section describes various primitive procedures which control the flow of program execution in special ways. The \text{procedure?} predicate is also described here.

\begin{align*}
(\text{procedure?} \ \text{obj}) & \quad \text{procedure} \\
\text{Returns} \ \#t \ \text{if} \ \text{obj} \ \text{is a procedure, otherwise} & \ \text{returns} \ \#f.
\end{align*}

\begin{align*}
(\text{procedure?} \ \text{car}) & \Rightarrow \#t \\
(\text{procedure?} \ \text{'}\text{car}) & \Rightarrow \#f \\
(\text{procedure?} \ \text{\lambda} (x) (* x x)) & \Rightarrow \#t \\
(\text{procedure?} \ \text{\'}(\text{\lambda} (x) (* x x))) & \Rightarrow \#f \\
(\text{call-with-current-continuation} \ \text{procedure?}) & \Rightarrow \#t
\end{align*}

\begin{align*}
(\text{apply} \ \text{proc} \ \text{arg}_1 \ \ldots \ \text{args}) & \quad \text{procedure} \\
\text{The apply procedure calls} \ \text{proc} \ \text{with the elements of the list} & \ \text{(append} \ \text{list} \ \text{arg}_1 \ \ldots \ \text{args}) \ \text{as the actual arguments.}
\end{align*}

\begin{align*}
(\text{apply} + \ \text{(list} \ 3 \ 4)) & \Rightarrow 7 \\
(\text{define} \ \text{compose} \ \text{(lambda} (f \ g) \ \text{(lambda} \ \text{args} \ \text{(f} \ \text{(apply} \ g \ \text{args})))) & \\
(\text{((compose} \ \text{sqrt} *) \ 12 \ 75)) & \Rightarrow 30
\end{align*}

\begin{align*}
(\text{map} \ \text{proc} \ \text{list}_1 \ \text{list}_2 \ \ldots) & \quad \text{procedure} \\
\text{It is an error if} \ \text{proc} \ \text{does not accept as many arguments as there are} & \ \text{lists and return a single value. The map procedure applies} \ \text{proc} \ \text{element-wise to the elements of the lists and returns a list of the results, in order. If more than one list is given and not all lists have the same length, map terminates when the shortest list runs out. It is an error for proc to mutate any of the lists. The dynamic order in which proc is applied to the elements of the lists is unspecified. If multiple returns occur from map, the values returned by earlier returns are not mutated.}
\end{align*}

\begin{align*}
(\text{map} \ \text{cadr} \ \text{\'}(\text{\lambda} (a \ b) \ \text{\'}(d \ e) \ \text{\'}(g \ h))) & \Rightarrow \text{(b e h)} \\
(\text{map} \ \text{\lambda} (n) \ \text{(expt} n n) \ \text{\'}(1 \ 2 \ 3 \ 4 \ 5)) & \Rightarrow \text{(1 4 27 256 3125)} \\
(\text{map} + \ \text{\'}(1 \ 2 \ 3) \ \text{\'}(4 \ 5 \ 6 \ 7)) & \Rightarrow (5 \ 7 \ 9) \\
(\text{let} ((\text{count} 0)) \ \text{(map} \ \text{\lambda} (\text{ignored}) \ \text{(set!} \ \text{count} \ (+ \ \text{count} 1)) \ \text{count} \ \text{\'}(a \ b))) & \Rightarrow \text{(1 2 or 2 1)}
\end{align*}

\begin{align*}
(\text{string-map} \ \text{proc} \ \text{string}_1 \ \text{string}_2 \ \ldots) & \quad \text{procedure} \\
\text{It is an error if} \ \text{proc} \ \text{does not accept as many arguments as there are} & \ \text{strings and return a single character. The string-map procedure applies proc element-wise to the elements of the strings and returns a string of the results, in order. If more than one string is given and not all strings have the same length, string-map terminates when the shortest string runs out. The dynamic order in which proc is applied to the elements of the strings is unspecified. If multiple returns occur from string-map, the values returned by earlier returns are not mutated.}
\end{align*}

\begin{align*}
(\text{string-map} \ \text{char-foldcase} \ \text{"AbdEgH"}) & \Rightarrow \text{"abdeg"} \\
(\text{string-map} \ \text{\lambda} (c) \ \text{\textbf{(integer->char}} (+ 1 (\text{char->integer} c))) \ \text{\"HAL"}) & \Rightarrow \text{"IBM"} \\
(\text{string-map} \ \text{\lambda} (c \ k) \ \text{\textbf{(if}} (\text{eqv?} \ k \ \text{\#u)} \ \text{char-upcase} \ \text{char-downcase}) \ c)) \ \text{\"studlycaps xxx"} \ \text{\"ululululul"}) & \Rightarrow \text{"StUdLyCaPs"}
\end{align*}

\begin{align*}
(\text{vector-map} \ \text{proc} \ \text{vector}_1 \ \text{vector}_2 \ \ldots) & \quad \text{procedure} \\
\text{It is an error if} \ \text{proc} \ \text{does not accept as many arguments as there are vectors and return a single value. The vector-map procedure applies proc element-wise to the elements of the vectors and returns a vector of the results,}
\end{align*}
in order. If more than one vector is given and not all vectors have the same length, vector-map terminates when the shortest vector runs out. The dynamic order in which proc is applied to the elements of the vectors is unspecified. If multiple returns occur from vector-map, the values returned by earlier returns are not mutated.

\[
\text{(vector-map cdr 'a b d e g h)} \implies \text{(#b e h)}
\]

\[
\text{(vector-map (lambda (n) (expt n n)) '1 2 3 4 5)} \implies \text{(#1 4 27 256 3125)}
\]

\[
\text{(vector-map + '#(1 2 3) '#(4 5 6 7))} \implies \text{(#5 7 9)}
\]

\[
\text{(let ((v (make-vector 5)))}
\]

\[
\text{(vector-map (lambda (i) (list-set! v i (* i i))) 'a b))} \implies \text{(#1 2) or #2 1}
\]

\[
\text{(for-each proc list1 list2 ...)} \implies \text{procedure}
\]

The arguments to for-each are like the arguments to map, but for-each calls proc for its side effects rather than for its values. Unlike map, for-each is guaranteed to call proc on the elements of the lists in order from the first element(s) to the last, and the value returned by for-each is unspecified. If more than one list is given and not all lists have the same length, for-each terminates when the shortest list runs out. It is an error for proc to mutate any of the lists.

\[
\text{(let ((v (make-vector 5)))}
\]

\[
\text{(for-each (lambda (i) (vector-set! v i (* i i))) v)} \implies \text{(#0 1 4 9 16)}
\]

\[
\text{(string-for-each proc string1 string2 ...)} \implies \text{procedure}
\]

The arguments to string-for-each are like the arguments to string-map, but string-for-each calls proc for its side effects rather than for its values. Unlike string-map, string-for-each is guaranteed to call proc on the elements of the lists in order from the first element(s) to the last, and the value returned by string-for-each is unspecified. If more than one string is given and not all strings have the same length, string-for-each terminates when the shortest string runs out. It is an error for proc to mutate any of the strings.

\[
\text{(let ((v '()))}
\]

\[
\text{(string-for-each (lambda (c) (set! v (cons (char->integer c) v))) "abcde") v)} \implies \text{(101 100 99 98 97)}
\]

\[
\text{(vector-for-each proc vector1 vector2 ...)} \implies \text{procedure}
\]

The arguments to vector-for-each are like the arguments to vector-map, but vector-for-each calls proc for its side effects rather than for its values. Unlike vector-map, vector-for-each is guaranteed to call proc on the elements of the vectors in order from the first element(s) to the last, and the value returned by vector-for-each is unspecified. If more than one vector is given and not all vectors have the same length, vector-for-each terminates when the shortest vector runs out. It is an error for proc to mutate any of the vectors.

\[
\text{(let ((v (make-list 5)))}
\]

\[
\text{(vector-for-each (lambda (i) (list-set! v i (* i i))) '0 1 2 3 4) v)} \implies \text{(0 1 4 9 16)}
\]

\[
\text{(call-with-current-continuation proc) \implies \text{procedure}}
\]

\[
\text{(call/cc proc) \implies \text{procedure}}
\]

It is an error if proc does not accept one argument. The procedure call-with-current-continuation (or its equivalent abbreviation call/cc) packages the current continuation (see the rationale below) as an “escape procedure” and passes it as an argument to proc. The escape procedure is a Scheme procedure that, if it is later called, will abandon whatever continuation is in effect at that later time and will instead use the continuation that was in effect when the escape procedure was created. Calling the escape procedure may cause the invocation of before and after thunks installed using dynamic-wind.

The escape procedure accepts the same number of arguments as the continuation to the original call to call-with-current-continuation. Except for continuations created by the call-with-values procedure (including the initialization expressions of let-values and let*-values expressions), all continuations take exactly one value. The effect of passing no value or more than one value to continuations that were not created by call-with-values is unspecified.

However, the continuations of all non-final expressions within a sequence of expressions, such as in lambda, case-lambda, begin, let, let*, letrec, letrec*, let-values, let*-values, let-syntx, letrec-syntx, parameterize, guard, case, cond, when, and unless expressions, take an arbitrary number of values, because they discard the values passed to them in any event.

The escape procedure that is passed to proc has unlimited extent just like any other procedure in Scheme. It can be stored in variables or data structures and can be called as many times as desired.

The following examples show only the simplest ways in which call-with-current-continuation is used. If
all real uses were as simple as these examples, there
would be no need for a procedure with the power of
call-with-current-continuation.

(call-with-current-continuation
  (lambda (exit)
    (for-each (lambda (x)
                  (if (negative? x)
                      (exit x)))
      '(54 0 37 -3 245 19))
    #t))  ⇒ -3

(define list-length
  (lambda (obj)
    (call-with-current-continuation
     (lambda (return)
      (letrec ((r
                    (lambda (obj)
                      (cond ((null? obj) 0)
                            ((pair? obj)
                             (+ (r (cdr obj)) 1))
                            (else (return #f))))))
        (r obj))))))

(list-length '(1 2 3 4))  ⇒ 4
(list-length '(a b . c))  ⇒ #f

Rationale:

A common use of call-with-current-continuation is for
structured, non-local exits from loops or procedure bodies, but
in fact call-with-current-continuation is useful for imple-
menting a wide variety of advanced control structures.

Whenever a Scheme expression is evaluated there is a con-
tinuation wanting the result of the expression. The continuation
represents an entire (default) future for the computation. If the
expression is evaluated at top level, for example, then the con-
tinuation might take the result, print it on the screen, prompt
for the next input, evaluate it, and so on forever. Most of the
time the continuation includes actions specified by user code,
as in a continuation that will take the result, multiply it by the
value stored in a local variable, add seven, and give the answer
to the top level continuation to be printed. Normally these
ubiquitous continuations are hidden behind the scenes and pro-
grammers do not think much about them. On rare occasions,
however, a programmer needs to deal with continuations explic-
itly. The call-with-current-continuation procedure allows
Scheme programmers to do that by creating a procedure that acts
just like the current continuation.

Most programming languages incorporate one or more special-
purpose escape constructs with names like exit, return, or
even goto. In 1965, however, Peter Landin [23] invented a
general purpose escape operator called the J-operator. John
Reynolds [32] described a simpler but equally powerful con-
struct in 1972. The catch syntax described by Sussman and
Steele in the 1975 report on Scheme is exactly the same as
Reynolds's construct, though its name came from a less general
construct in MacLisp. Several Scheme implementors noticed
that the full power of catch could be provided by a proce-
dure instead of by a special syntactic construct, and the name
call-with-current-continuation was coined in 1982. This
name is descriptive, but opinions differ on the merits of such a
long name, and some people prefer the name call/cc instead.

(values obj ...)  procedure

Delivers all of its arguments to its continuation. The
values procedure might be defined as follows:

(define (values . things)
  (call-with-current-continuation
   (lambda (cont) (apply cont things))))

(call-with-values (lambda () (values 4 5))
  (lambda (a b) b))  ⇒ 5
(call-with-values * -)  ⇒ -1

(dynamic-wind before thunk after)  procedure

Calls thunk without arguments, returning the result(s) of
this call. Before and after are called, also without ar-
guements, as required by the following rules. Note that,
in the absence of calls to continuations captured using
call-with-current-continuation, the three arguments
are called once each, in order. Before is called wher-
ever execution enters the dynamic extent of the call to
thunk and after is called whenever it exits that dynamic
extent. The dynamic extent of a procedure call is the pe-
riod between when the call is initiated and when it returns.
Before and after are excluded from the dynamic extent. In
Scheme, because of call-with-current-continuation,
the dynamic extent of a call is not always a single, con-
nected time period. It is defined as follows:

- The dynamic extent is entered when execution of the
  body of the called procedure begins.
- The dynamic extent is also entered when execu-
tion is not within the dynamic extent and a
  continuation is invoked that was captured (using
call-with-current-continuation) during the dy-
namic extent.
- It is exited when the called procedure returns.
• It is also exited when execution is within the dynamic extent and a continuation is invoked that was captured while not within the dynamic extent.

If a second call to `dynamic-wind` occurs within the dynamic extent of the call to `thunk` and then a continuation is invoked in such a way that the `afters` from these two invocations of `dynamic-wind` are both to be called, then the `after` associated with the second (inner) call to `dynamic-wind` is called first.

If a second call to `dynamic-wind` occurs within the dynamic extent of the call to `thunk` and then a continuation is invoked in such a way that the `befores` from these two invocations of `dynamic-wind` are both to be called, then the `before` associated with the first (outer) call to `dynamic-wind` is called first.

The effect of using a captured continuation to enter or exit the dynamic extent of a call to `before` or `after` is unspecified.

```
(let ((path '())
  (c #f))
(let ((add (lambda (s)
             (set! path (cons s path)))))
  (dynamic-wind
   (lambda () (add 'connect))
   (lambda ()
    (add (call-with-current-continuation
          (lambda (c0)
            (set! c c0)
            'talk1))))
   (lambda () (add 'disconnect)))
  (if (< (length path) 4)
    (c 'talk2)
    (reverse path))))
⇒ (connect talk1 disconnect
     connect talk2 disconnect)
```

### 6.11. Exceptions

This section describes Scheme’s exception-handling and exception-raising procedures. For the concept of Scheme exceptions, see section 1.3.2. See also 4.2.7 for the `guard` syntax.

**Exception handlers** are one-argument procedures that determine the action the program takes when an exceptional situation is signalled. The system implicitly maintains a current exception handler.

The program raises an exception by invoking the current exception handler, passing it an object encapsulating information about the exception. Any procedure accepting one argument may serve as an exception handler and any object may be used to represent an exception.

```
(with-exception-handler handler thunk) procedure
```

It is an error if `handler` does not accept one argument. It is also an error if `thunk` does not accept zero arguments. The `with-exception-handler` procedure returns the results of invoking `thunk`. `Handler` is installed as the current exception handler for the dynamic extent (as determined by `dynamic-wind`) of the invocation of `thunk`.

```
(raise obj) procedure
```

Raises an exception by invoking the current exception handler on `obj`. The handler is called with a continuation whose dynamic extent is that of the call to `raise`, except that the current exception handler is the one that was in place when the handler being called was installed. If the handler returns, an exception is raised in the same dynamic extent as the handler.

```
(raise-continuable obj) procedure
```

Raises an exception by invoking the current exception handler on `obj`. The handler is called with a continuation that is equivalent to the continuation of the call to `raise-continuable`, except that: (1) the current exception handler is the one that was in place when the handler being called was installed, and (2) if the handler being called returns, then it will again become the current exception handler. If the handler returns, the values it returns become the values returned by the call to `raise-continuable`.

```
(error message obj ...) procedure
```

`Message` should be a string. Raises an exception as if by calling `raise` on a newly allocated implementation-defined object which encapsulates the information provided by `message`, as well as any `objs`, known as the *irritants*. The procedure `error-object?` must return `#t` on such objects.
(define (null-list? l)
  (cond ((pair? l) #f)
        ((null? l) #t)
        (else
          (error
           "null-list?: argument out of domain" l)))))

(error-object? obj) procedure
Returns #t if obj is an object created by error or one of an implementation-defined set of objects. Otherwise, it returns #f.

(error-object-message error-object) procedure
Returns the message encapsulated by error-object.

(error-object-irritants error-object) procedure
Returns a list of the irritants encapsulated by error-object.

6.12. Eval

(eval expression environment-specifier) eval library procedure
Evaluates expression in the specified environment and returns its value. It is an error if expression is not a valid Scheme expression represented as a datum. Implementations may extend eval to allow non-expression programs such as definitions as the first argument, with the restriction that eval is not allowed to create new bindings in the environments returned by null-environment or scheme-report-environment.

(eval '(+ 7 3) (scheme-report-environment 7))
⇒ 21

(let ((f (eval '(lambda (f x) (f x x))
               (null-environment 7))))
  (f + 10))
⇒ 20

(scheme-report-environment version) eval library procedure
If version is equal to 7, corresponding to this revision of the Scheme report (the Revised7 Report on Scheme), the scheme-report-environment procedure returns a specifier for an environment that contains only the bindings for all syntactic keywords defined either in the base library or in the other libraries of this report, provided that the implementation supports them. Implementations must support this value of version.

Implementations may also support other values of version, in which case they should return an environment containing bindings corresponding to the corresponding version of the report. If version is neither 7 nor another value supported by the implementation, an error is signalled.

The effect of assigning (through the use of eval) a variable bound in a scheme-report-environment (for example car) is unspecified. Thus the environments specified by scheme-report-environment may be immutable.

(null-environment version) eval library procedure
If version is equal to 7, corresponding to this revision of the Scheme report (the Revised7 Report on Scheme), the null-environment procedure returns a specifier for an environment that contains only the bindings for all syntactic keywords defined either in the base library or in the other libraries of this report, provided that the implementation supports them. Implementations must support this value of version.

Implementations may also support other values of version, in which case they should return an environment containing bindings corresponding to the corresponding version of the report. If version is neither 7 nor another value supported by the implementation, an error is signalled.

(environment list1 ...) eval library procedure
This procedure returns a specifier for the environment that results by starting with an empty environment and then importing each list, considered as an import set, into it. (See section 5.5 for a description of import sets.) The bindings of the environment represented by the specifier are immutable.

(interaction-environment) repl library procedure
This procedure returns a specifier for an environment that contains an implementation-defined set of bindings, typically a superset of those exported by (scheme base). The intent is that this procedure will return the environment in which the implementation would evaluate expressions entered by the user into a REPL.

6.13. Input and output

6.13.1. Ports

Ports represent input and output devices. To Scheme, an input port is a Scheme object that can deliver data upon command, while an output port is a Scheme object that can accept data. Whether the input and output port types are disjoint is implementation-dependent.
Different port types operate on different data. Scheme implementations are required to support textual ports and binary ports, but may also provide other port types.

A textual port supports reading or writing of individual characters from or to a backing store containing characters using read-char and write-char below, as well as operations defined in terms of characters such as read and write.

A binary port supports reading or writing of individual bytes from or to a backing store containing bytes using read-u8 and write-u8 below, as well as operations defined in terms of bytes. Whether the textual and binary port types are disjoint is implementation-dependent.

Ports can be used to access files, devices, and similar things on the host system on which the Scheme program is running.

(call-with-input-file string proc)

file library procedure

(call-with-output-file string proc)

file library procedure

It is an error if proc does not accept one argument. For call-with-input-file, the file named by string should already exist; for call-with-output-file, the effect is unspecified if the file already exists. These procedures call proc with one argument: the textual port obtained by opening the named file for input or output as if by open-input-file or open-output-file. If the file cannot be opened, an error is signalled. If proc returns, then the port is closed automatically and the values yielded by the proc are returned. If proc does not return, then the port must not be closed automatically unless it is possible to prove that the port will never again be used for a read or write operation.

Rationale: Because Scheme's escape procedures have unlimited extent, it is possible to escape from the current continuation but later to escape back in. If implementations were permitted to close the port on any escape from the current continuation, then it would be impossible to write portable code using both call-with-current-continuation and call-with-input-file or call-with-output-file.

(call-with-port port proc)

procedure

It is an error if proc does not accept one argument. The call-with-port procedure calls proc with port as an argument. If proc returns, port is closed automatically and the values returned by proc are returned.

(input-port? obj)

procedure

(output-port? obj)

procedure

(textual-port? obj)

procedure

These procedures return #t if obj is an input port, output port, textual port, binary port, or any kind of port, respectively. Otherwise they return #f.

(port-open? port)

procedure

Returns #t if port is still open and capable of performing input or output, and #f otherwise.

(current-input-port)

procedure

(current-output-port)

procedure

(current-error-port)

procedure

Returns the current default input port, output port, or error port (an output port), respectively. These procedures are parameter objects, which can be overridden with parameterize (see section 4.2.6). The initial bindings for these are system-defined textual ports.

(with-input-from-file string thunk)

file library procedure

(with-output-to-file string thunk)

file library procedure

For with-input-from-file, it is an error if the file named by string does not already exist; for with-output-to-file, the effect is unspecified if the file already exists. The file is opened for input or output as if by open-input-file or open-output-file, and the new port is made the default value returned by current-input-port or current-output-port (and is used by (read), (write obj), and so forth). The thunk is then called with no arguments. When the thunk returns, the port is closed and the previous default is restored. It is an error if thunk does not accept zero arguments. Both procedures return the values yielded by thunk. If an escape procedure is used to escape from the continuation of these procedures, their behavior is implementation-dependent.

(open-input-file string)

file library procedure

(open-binary-input-file string)

file library procedure

Takes a string for an existing file and returns a textual input port or binary input port capable of delivering data from the file. If the file cannot be opened, an error is signalled.

(open-output-file string)

file library procedure

(open-binary-output-file string)

file library procedure

Takes a string naming an output file to be created and returns a textual output port or binary output port capable
of writing data to a new file by that name. If the file cannot
be opened, an error is signalled. If a file with the given
name already exists, the effect is unspecified.

```
(close-port port) procedure
(close-input-port port) procedure
(close-output-port port) procedure
```

Closes the resource associated with port, rendering the port
incapable of delivering or accepting data. It is an error to
apply the last two procedures to a port which is not an
input or output port, respectively. Scheme implementations
may provide ports which are simultaneously input and output ports, such as sockets; the close-input-port and close-output-port procedures can then be used to
close the input and output sides of the port independently.

These routines have no effect if the file has already been
closed. The value returned is unspecified.

```
(open-input-string string) procedure
(Takes a string and returns a textual input port that delivers
characters from the string.

(open-output-string) procedure
Returns a textual output port that will accumulate char-
acters for retrieval by get-output-string.

(get-output-string port) procedure
It is an error if port was not created with
open-output-string. Returns a string consisting of
the characters that have been output to the port so far in
the order they were output.

(open-input-bytevector bytevector) procedure
(Takes a bytevector and returns a binary input port that
delivers bytes from the bytevector.

(open-output-bytevector) procedure
Returns a binary output port that will accumulate bytes
for retrieval by get-output-bytevector.

(get-output-bytevector port) procedure
It is an error if port was not created with
open-output-bytevector. Returns a bytevector consist-
ing of the bytes that have been output to the port so far
in the order they were output.

6.13.2. Input

```
(read) read library procedure
(read port) read library procedure
```

The read procedure converts external representations of
Scheme objects into the objects themselves. That is, it is
a parser for the nonterminal ⟨datum⟩ (see sections 7.1.2
and 6.4). It returns the next object parsable from the
given textual input port, updating port to point to the
first character past the end of the external representation
of the object.

If an end of file is encountered in the input before any char-
acters are found that can begin an object, then an end-of-
file object is returned. The port remains open, and further
attempts to read will also return an end-of-file object. If an
end of file is encountered after the beginning of an object’s
external representation, but the external representation is
incomplete and therefore not parsable, an error is signalled.

Port may be omitted, in which case it defaults to the value
returned by current-input-port. It is an error to read
from a closed port.

```
(read-char) procedure
(read-char port) procedure
```

Returns the next character available from the textual input
port, updating the port to point to the following character. If
no more characters are available, an end-of-file object is
returned. Port may be omitted, in which case it defaults
to the value returned by current-input-port.

```
(peek-char) procedure
(peek-char port) procedure
```

Returns the next character available from the textual input
port, without updating the port to point to the following character. If
no more characters are available, an end-of-file object is
returned. Port may be omitted, in which case it defaults
to the value returned by current-input-port.

Note: The value returned by a call to peek-char is the same as
the value that would have been returned by a call to read-char
with the same port. The only difference is that the very next call
to read-char or peek-char on that port will return the value
returned by the preceding call to peek-char. In particular, a
call to peek-char on an interactive port will hang waiting for
input whenever a call to read-char would have hung.

```
(read-line) procedure
(read-line port) procedure
```

Returns the next line of text available from the textual input
port, updating the port to point to the following character. If an end of line is read, a string containing all
of the text up to (but not including) the end of line is returned, and the port is updated to point just past the end of line. If an end of file is encountered before any end of line is read, but some characters have been read, a string containing those characters is returned. If an end of file is encountered before any characters are read, an end-of-file object is returned. For the purpose of this procedure, an end of line consists of either a linefeed character, a carriage return character, or a sequence of a carriage return character followed by a linefeed character. Implementations may also recognize other end of line characters or sequences. Port may be omitted, in which case it defaults to the value returned by current-input-port.

\((\text{eof-object? } \text{obj})\) procedure

Returns #t if \text{obj} is an end-of-file object, otherwise returns #f. The precise set of end-of-file objects will vary among implementations, but in any case no end-of-file object will ever be an object that can be read in using \text{read}.

\((\text{char-ready?})\) procedure

\((\text{char-ready? } \text{port})\) procedure

Returns #t if a character is ready on the textual input \text{port} and returns #f otherwise. If \text{char-ready?} returns #t then the next \text{read-char} operation on the given \text{port} is guaranteed not to hang. If the \text{port} is at end of file then \text{char-ready?} returns #t. Port may be omitted, in which case it defaults to the value returned by current-input-port.

Rationale: The \text{char-ready?} procedure exists to make it possible for a program to accept characters from interactive ports without getting stuck waiting for input. Any input editors associated with such ports must ensure that characters whose existence has been asserted by \text{char-ready?} cannot be removed from the input. If \text{char-ready?} were to return #f at end of file, a port at end-of-file would be indistinguishable from an interactive port that has no ready characters.

\((\text{read-u8})\) procedure

\((\text{read-u8 } \text{port})\) procedure

Returns the next byte available from the binary input \text{port}, updating the \text{port} to point to the following byte. If no more bytes are available, an end-of-file object is returned. Port may be omitted, in which case it defaults to the value returned by current-input-port.

\((\text{peek-u8})\) procedure

\((\text{peek-u8 } \text{port})\) procedure

Returns the next byte available from the binary input \text{port}, without updating the \text{port} to point to the following byte.

If no more bytes are available, an end-of-file object is returned. Port may be omitted, in which case it defaults to the value returned by current-input-port.

\((\text{u8-ready?})\) procedure

\((\text{u8-ready? } \text{port})\) procedure

Returns #t if a byte is ready on the binary input \text{port} and returns #f otherwise. If \text{u8-ready?} returns #t then the next \text{read-u8} operation on the given \text{port} is guaranteed not to hang. If the \text{port} is at end of file then \text{u8-ready?} returns #t. Port may be omitted, in which case it defaults to the value returned by current-input-port.

\((\text{read-bytevector length})\) procedure

\((\text{read-bytevector length } \text{port})\) procedure

\((\text{read-bytevector! bytevector start end})\) procedure

\((\text{read-bytevector! bytevector start end } \text{port})\) procedure

Reads the next \text{length} bytes, or as many as are available before the end of file, from the binary input \text{port} into a newly allocated bytevector in left-to-right order and returns the bytevector. If no bytes are available before the end of file, an end-of-file object is returned. Port may be omitted, in which case it defaults to the value returned by current-input-port.

\((\text{write obj})\) write library procedure

\((\text{write obj } \text{port})\) write library procedure

Writes a representation of \text{obj} to the given textual output \text{port}. Strings that appear in the written representation are enclosed in double quotes, and within those strings backslash and double quote characters are escaped by backslashes. Symbols that contain non-ASCII characters are escaped either with inline hex escapes or with vertical bars. Character objects are written using the #\ notation. Shared list structure is represented using datum labels. The \text{write} procedure returns an unspecified value. Port may be omitted, in which case it defaults to the value returned by current-output-port.
The `write-simple` procedure is the same as `write`, except that shared structure is not represented using datum labels. This may cause `write-simple` not to terminate if `obj` contains circular structure.

Writes a representation of `obj` to the given textual output `port`. Strings that appear in the representation are not enclosed in double quotes, and no characters are escaped within those strings. The `display` procedure returns an unspecified value. `Port` may be omitted, in which case it defaults to the value returned by `current-output-port`.

Rationale: The `write` procedure is intended for producing machine-readable output and `display` for producing human-readable output.

Writes an end of line to textual output `port`. Exactly how this is done differs from one operating system to another. Returns an unspecified value. `Port` may be omitted, in which case it defaults to the value returned by `current-output-port`.

Rationale: For portability, `load` must operate on source files. Its operation on other kinds of files necessarily varies among implementations.

An implementation-dependent operation is used to transform `filename` into the name of an existing file containing Scheme source code. The `load` procedure reads expressions and definitions from the file and evaluates them sequentially in the environment specified by `environment-specifier`. If `environment-specifier` is omitted, `(interaction-environment)` is assumed.

It is unspecified whether the results of the expressions are printed. The `load` procedure does not affect the values returned by `current-input-port` and `current-output-port`. It returns an unspecified value.

Rationale: If `filename` is not a string, the `file-exists?` procedure returns `#t` if the named file exists at the time the procedure is called, and `#f` otherwise.

It is an error if `filename` is not a string. The `delete-file` procedure deletes the named file if it exists and can be deleted, and returns an unspecified value. If the file does not exist or cannot be deleted, an error is signalled.
(command-line) process-context library procedure

Returns the command line passed to the process as a list of strings. The first string corresponds to the command name, and is implementation-dependent. It is an error to mutate any of these strings.

(exit) process-context library procedure
(exit obj) process-context library procedure

Exits the running program and communicates an exit value to the operating system. If no argument is supplied, the exit procedure should communicate to the operating system that the program exited normally. If an argument is supplied, the exit procedure should translate the argument into an appropriate exit value for the operating system. If obj is #f, the exit is assumed to be abnormal.

(get-environment-variable name) process-context library procedure

Most operating systems provide each running process with an environment consisting of environment variables. (This environment is not to be confused with the Scheme environments that can be passed to eval: see section 6.12) Both the name and value of an environment variable are strings. The procedure get-environment-variable returns the value of the environment variable name, or #f if the named environment variable is not found. get-environment-variable may use locale-setting information to encode the name and decode the value of the environment variable. It is an error if get-environment-variable can’t decode the value. It is also an error to mutate the resulting string.

(get-environment-variable "PATH")
⇒ "/usr/local/bin:/usr/bin:/bin"

(get-environment-variables) process-context library procedure

Returns the names and values of all the environment variables as an alist, where the car of each entry is the name of an environment variable and the cdr is its value, both as strings. The order of the list is unspecified. It is an error to mutate any of these strings.

(get-environment-variables)
⇒ ("USER" . "root") ("HOME" . "/")

(current-second) time library procedure

Returns an inexact number representing the current time on the International Atomic Time (TAI) scale. The value 0.0 represents ten seconds after midnight on January 1, 1970 TAI (equivalent to midnight Universal Time) and the value 1.0 represents one TAI second later. Neither high accuracy nor high precision are required; in particular, returning Coordinated Universal Time plus a suitable constant may be the best an implementation can do.

(current-jiffy) time library procedure

Returns the number of jiffies as an exact integer that have elapsed since an arbitrary, implementation-defined epoch. A jiffy is an implementation-defined fraction of a second which is defined by the return value of the jiffies-per-second procedure. The starting epoch is guaranteed to be constant during a run of the program, but may vary between different runs.

(jiffies-per-second) time library procedure

Returns an exact integer representing the number of jiffies per SI second. This value is an implementation-specified constant.

(define (time-length)
  (let ((list (make-list 100000))
        (start (current-jiffy)))
    (/ (- (current-jiffy) start)
       (jiffies-per-second))))
7. Formal syntax and semantics

This chapter provides formal descriptions of what has already been described informally in previous chapters of this report.

7.1. Formal syntax

This section provides a formal syntax for Scheme written in an extended BNF.

All spaces in the grammar are for legibility. Case is insignificant; for example, \#x1A and \#X1a are equivalent. (empty) stands for the empty string.

The following extensions to BNF are used to make the description more concise: (thing)\* means zero or more occurrences of (thing); and (thing)\+ means at least one (thing).

7.1.1. Lexical structure

This section describes how individual tokens (identifiers, numbers, etc.) are formed from sequences of characters. The following sections describe how expressions and programs are formed from sequences of tokens.

(Intertoken space) may occur on either side of any token, but not within a token.

Identifiers that do not begin with a vertical bar are terminated by a (delimiter) or by the end of the input. So are dot, numbers, characters, and booleans. Identifiers that begin with a vertical bar are terminated by another vertical bar.

The following four characters from the ASCII repertoire are reserved for future extensions to the language: [ ] { }

In addition to the identifier characters of the ASCII repertoire specified below, Scheme implementations may permit any additional repertoire of Unicode characters to be employed in identifiers, provided that each such character has a Unicode general category of Lu, Li, Lt, Lm, Lo, Mn, Me, Me, Nd, Nl, No, Pd, Pc, Po, Sc, Sm, Sk, So, or Co, or is U+200C or U+200D (the zero-width non-joiner and joiner, respectively, which are needed for correct spelling in Persian, Hindi, and other languages). It is an error to use a non-Unicode character in symbols or identifiers.

All Scheme implementations must permit the escape sequence \x<hexdigits>; to appear in Scheme identifiers. If the character with the given Unicode scalar value is supported by the implementation, identifiers containing such a sequence are equivalent to identifiers containing the corresponding character.

\(\text{token} \rightarrow \langle \text{identifier} \rangle | \langle \text{boolean} \rangle | \langle \text{number} \rangle | \langle \text{character} \rangle | \langle \text{string} \rangle\)
The following rules for \(\langle\text{num}\rangle\), \(\langle\text{complex}\rangle\), \(\langle\text{real}\rangle\), \(\langle\text{integer}\rangle\), \(\langle\text{prefix}\rangle\) and \(\langle\text{suffix}\rangle\) are implicitly replicated for \(R = 2, 8, 10, 16\). There are no rules for \(\langle\text{decimal}\ 2\rangle\), \(\langle\text{decimal}\ 8\rangle\), and \(\langle\text{decimal}\ 16\rangle\), which means that numbers containing decimal points or exponents are always in decimal radix. Although not shown below, all
alphanumeric characters used in the grammar of numbers may appear in either upper or lower case.

\[
\begin{align*}
\langle\text{num}\rangle & \rightarrow \langle\text{prefix}\rangle \langle\text{complex}\rangle \\
\langle\text{complex}\rangle & \rightarrow \langle\text{real}\rangle \mid \langle\text{real}\rangle \#\langle\text{real}\rangle \\
\langle\text{real}\rangle & \rightarrow \langle\text{real}\rangle + \langle\text{real}\rangle \mid \langle\text{real}\rangle - \langle\text{real}\rangle \\
\langle\text{integer}\rangle & \rightarrow \langle\text{integer}\rangle / \langle\text{integer}\rangle \\
\langle\text{decimal}\rangle & \rightarrow \langle\text{integer}\rangle \langle\text{suffix}\rangle \\
\langle\text{suffix}\rangle & \rightarrow \langle\text{empty}\rangle \\
\langle\text{empty}\rangle & \rightarrow (\langle\text{exponent marker}\rangle \langle\text{sign}\rangle \langle\text{digit}\rangle)^+ \\
\langle\text{exponent marker}\rangle & \rightarrow \text{e} \mid \text{s} \mid \text{f} \mid \text{d} \mid 1 \\
\langle\text{sign}\rangle & \rightarrow \langle\text{empty}\rangle \mid + \mid - \\
\langle\text{exactness}\rangle & \rightarrow \langle\text{empty}\rangle \mid \#i \mid \#d \\
\langle\text{radix}\ 2\rangle & \rightarrow \#b \\
\langle\text{radix}\ 8\rangle & \rightarrow \#0 \\
\langle\text{radix}\ 10\rangle & \rightarrow \langle\text{empty}\rangle \mid \#d \\
\langle\text{radix}\ 16\rangle & \rightarrow \#x \\
\langle\text{digit}\ 2\rangle & \rightarrow 0 \mid 1 \\
\langle\text{digit}\ 8\rangle & \rightarrow 0 \mid 1 \mid 2 \mid 3 \mid 4 \mid 5 \mid 6 \mid 7 \\

\( \text{(keyword)} \rightarrow (\text{identifier}) \)
\( \text{(macro block)} \rightarrow \)

\( \text{(let-syntax} \ ((\text{syntax spec})^{*} \ (\text{body})) \)
\( \text{| (letrec-syntax} \ ((\text{syntax spec})^{*} \ (\text{body})) \)
\( \text{\ (syntax spec))} \rightarrow ((\text{keyword}) \ (\text{transformer spec})) \)

7.1.4. Quasiquotations

The following grammar for quasiquote expressions is not context-free. It is presented as a recipe for generating an infinite number of production rules. Imagine a copy of the following rules for \( D = 1, 2, 3, \ldots \) \( D \) keeps track of the nesting depth.

\( \text{\ (quasiquotation)} \rightarrow (\text{quasiquotation} 1) \)
\( \text{| (qq template} 0 \text{)} \rightarrow (\text{expression}) \)
\( \text{| (quasiquotation} \ (\text{qq template} \ D) \)
\( \text{\ (qq template} \ D \text{)} \rightarrow (\text{\ (qq template or splice} \ D)^{*}) \)
\( \text{| (\ (qq template or splice} \ D)^{+} \ (\ (qq template} \ D)) \)
\( \text{| \ (qq template} \ D \text{)} \)
\( \text{| (unquotation} \ (\text{qq template} \ D + 1) \)
\( \text{| (vector qq template} \ D \text{)} \rightarrow (\#((\text{qq template or splice} \ D)^{*}) \)
\( \text{| (\ (qq template or splice} \ D)^{*} \ (\ (qq template} \ D - 1) \)
\( \text{| (unquote} \ (\text{qq template} \ D - 1) \)
\( \text{| (qq template or splice} \ D \text{)} \rightarrow (\text{qq template} \ D) \)
\( \text{| (splicing unquotation} \ D \)
\( \text{| (splicing unquotation} \ D \text{)} \rightarrow (\text{qq template} \ D - 1) \)
\( \text{| (unquote-splicing} \ (\text{qq template} \ D - 1) \)

In \( \text{(quasiquotation)s}, \ a \ (\text{list qq template} \ D) \) can sometimes be confused with either an \( \text{(unquotation} \ D) \) or a \( \text{(splicing unquotation} \ D) \). The interpretation as an \( \text{(unquotation} \) or \( \text{(splicing unquotation} \) takes precedence.

7.1.5. Transformers

\( \text{(transformer spec)} \rightarrow \)
\( \text{| (syntax-rules} ((\text{identifier})^{*}) \ (\text{syntax rule})^{*}) \)
\( \text{| (syntax-rules} \ (\text{identifier}) ((\text{identifier})^{*}) \ (\text{syntax rule})^{*}) \)
\( \text{| (\text{syntax rule)} \rightarrow ((\text{pattern}) \ (\text{template}))} \)
\( \text{| (pattern)} \rightarrow (\text{pattern identifier}) \)
\( \text{| (\text{underscore})} \)
\( \text{| (\text{(pattern})^{+} \ (\text{pattern})} \)
\( \text{| (\text{(pattern})^{+} \ (\text{pattern}) \ (\text{ellipsis}) \ (\text{pattern})^{*})} \)
\( \text{| (\text{(pattern})^{*} \ (\text{pattern}) \ (\text{ellipsis}) \ (\text{pattern})^{*})} \)
\( \text{. (pattern}) \)
\( \text{| \#((pattern)^{*})} \)

\( \text{(let} \ (\text{letrec-syntax} ((\text{syntax spec})^{*} \ (\text{body})) \)
\text{| (letrec-syntax} ((\text{syntax spec})^{*} \ (\text{body})) \)
\text{\ (syntax spec))} \rightarrow ((\text{keyword}) \ (\text{transformer spec})) \)
7.1.6. Programs and definitions

\[
\begin{align*}
\langle \text{program} \rangle & \to \langle \text{command or definition} \rangle^* \\
\langle \text{command or definition} \rangle & \to \langle \text{definition} \rangle \mid \langle \text{begin} \rangle \mid \langle \text{import} \rangle \mid \langle \text{define} \rangle \\

\langle \text{syntax definition} \rangle & \to \langle \text{define-syntax} \rangle \langle \text{keyword} \rangle \langle \text{transformer spec} \rangle \\
\end{align*}
\]

7.1.7. Libraries

\[
\begin{align*}
\langle \text{library} \rangle & \to \langle \text{define-library} \rangle \\
\langle \text{define-library} \rangle & \to \langle \text{library name} \rangle \langle \text{library declaration} \rangle^* \\
\langle \text{library name} \rangle & \to \langle \text{library name part} \rangle^* \\
\langle \text{library name part} \rangle & \to \langle \text{identifier} \rangle \mid \langle \text{integer} \rangle_{10} \\
\langle \text{library declaration} \rangle & \to \langle \text{export} \rangle \langle \text{export spec} \rangle^* \\
\langle \text{export} \rangle & \to \langle \text{import} \rangle \langle \text{command or definition} \rangle^* \\
\end{align*}
\]

7.2. Formal semantics

This section provides a formal denotational semantics for the primitive expressions of Scheme and selected built-in procedures. The concepts and notation used here are described in [37]; the notation is summarized below:

- \(\ldots\) sequence formation
- \(s \downarrow k\) \(k\)th member of the sequence \(s\) (1-based)
- \(#s\) length of sequence \(s\)
- \(s \downarrow t\) concatenation of sequences \(s\) and \(t\)
- \(s \downarrow k\) drop the first \(k\) members of sequence \(s\)
- \(t \rightarrow a, b\) McCarthy conditional “if \(t\) then \(a\) else \(b\)”
- \(\rho[x/i]\) substitution “\(\rho\) with \(x\) for \(i\)”
- \(x \in D\) injection of \(x\) into domain \(D\)
- \(x \mid D\) projection of \(x\) to domain \(D\)

The reason that expression continuations take sequences of values instead of single values is to simplify the formal treatment of procedure calls and multiple return values.

The boolean flag associated with pairs, vectors, and strings will be true for mutable objects and false for immutable objects.

The order of evaluation within a call is unspecified. We mimic that here by applying arbitrary permutations \textit{permute} and \textit{unpermute}, which must be inverses, to the arguments in a call before and after they are evaluated. This is not quite right since it suggests, incorrectly, that the order of evaluation is constant throughout a program (for any given number of arguments), but it is a closer approximation to the intended semantics than a left-to-right evaluation would be.

The storage allocator \texttt{new} is implementation-dependent,
but it must obey the following axiom: if $new \sigma \in L$, then $\sigma (new \sigma \mid L) \Downarrow 2 = false$.

The definition of $K$ is omitted because an accurate definition of $K$ would complicate the semantics without being very interesting.

If $P$ is a program in which all variables are defined before being referenced or assigned, then the meaning of $P$ is

$$\mathcal{E}[(\lambda \alpha \, (P')) \ (\text{undefined} \ldots)]$$

where $I^*$ is the sequence of variables defined in $P$, $P'$ is the sequence of expressions obtained by replacing every definition in $P$ by an assignment, (undefined) is an expression that evaluates to undefined, and $\mathcal{E}$ is the semantic function that assigns meaning to expressions.

### 7.2.1. Abstract syntax

- $K \in \text{Con}$ constants, including quotations
- $I \in \text{Ide}$ identifiers (variables)
- $E \in \text{Exp}$ expressions
- $\Gamma \in \text{Com} = \text{Exp}$ commands

### 7.2.2. Domain equations

| $\alpha \in L$ | locations |
| $\nu \in N$ | natural numbers |
| $T = \{false, true\}$ | booleans |
| $Q$ | symbols |
| $H$ | characters |
| $R$ | numbers |
| $E_p = L \times L \times T$ | pairs |
| $E_v = L^* \times T$ | vectors |
| $E_a = L^* \times T$ | strings |
| $M = \{false, true, null, undefined, unspecified\}$ | miscellaneous |
| $\phi \in F = L \times (E^* \rightarrow K \rightarrow C)$ | procedure values |
| $\epsilon \in E = Q + H + R + E_p + E_v + E_a + M + F$ | expressed values |
| $\sigma \in S = L \rightarrow (E \times T)$ | stores |
| $\rho \in U = \text{Ide} \rightarrow L$ | environments |
| $\theta \in C = S \rightarrow A$ | command continuations |
| $\kappa \in K = E^* \rightarrow C$ | expression continuations |
| $\lambda \in \text{Errors}$ | answers |
| $X$ | errors |

### 7.2.3. Semantic functions

- $\mathcal{K} : \text{Con} \rightarrow \mathcal{E}$
- $\mathcal{E} : \text{Exp} \rightarrow U \rightarrow K \rightarrow C$
- $\mathcal{E}^* : \text{Exp}^* \rightarrow U \rightarrow K \rightarrow C$
- $\mathcal{C} : \text{Com}^* \rightarrow U \rightarrow C \rightarrow C$

Definition of $K$ deliberately omitted.

$$\mathcal{E}[(E_0 \ E^*)] = \lambda \rho \kappa. \mathcal{E}^*(\text{permute}(E_0 \downarrow E^*))$$

$$\rho (\lambda \epsilon. \mathcal{E}(\text{applicate}(\epsilon \downarrow 1) \ (\epsilon \downarrow 1) \ k))$$

$$\mathcal{E}[(\text{if } E_0 \ E_1 \ E_2)] = \lambda \rho \kappa. \mathcal{E}[\text{expr}(\lambda x. \epsilon \rightarrow \mathcal{E}[E_1] \ k, \ \mathcal{E}[E_2] \ k)]$$

$$\mathcal{E}[(\text{if } E_0 \ E_1)] = \lambda \rho \kappa. \mathcal{E}[\text{expr}(\lambda x. \epsilon \rightarrow \mathcal{E}[E_1] \ k, \ \text{send unspecified} \ k)]$$

Here and elsewhere, any expressed value other than undefined may be used in place of unspecified.
\[ E[(\text{set} \ 1 \ E)] = \lambda \rho \kappa . E[E] \rho (\text{single}(\lambda \epsilon . \text{assign} \ (\text{lookup} \ \rho \ I) \\
\epsilon) \ (\text{send} \ \text{unspecified} \ \kappa)) \]

\[ E[\square] = \lambda \rho \kappa . \kappa() \]

\[ E[E_0 \ E^*] = \lambda \rho \kappa . E[E_0]\rho (\text{single}(\lambda \epsilon_0 . \ E^*[E^*] \ \rho (\lambda \epsilon^*. \ \kappa (\langle \epsilon_0 \rangle \ # \epsilon^*)))) \]

\[ C[\square] = \lambda \rho \theta . \theta \]

\[ C[C_0 \ \Gamma^*] = \lambda \rho \theta . E[C_0]\rho (\lambda \epsilon^*. \ C[\Gamma^*] \ \rho \theta) \]

\text{twoarg (λe1 e2 k. \text{applicate} ϵ_1 (λe. \text{applicate} ϵ_2 e*)}
\]
The following `letrec` macro uses the symbol `<undefined>` in place of an expression which returns something that when stored in a location makes it an error to try to obtain the value stored in the location (no such expression is defined in Scheme). A trick is used to generate the temporary names needed to avoid specifying the order in which the values are evaluated. This could also be accomplished by using an auxiliary macro.

```
(define-syntax letrec
  (syntax-rules ()
    ((letrec ((var1 init1) ...) body ...)
      (letrec "generate_temp_names"
        (var1 ...) ()
        ((var1 init1) ...) body ...))
    (let ((var1 <undefined>) ...) (let ((temp1 init1) ...) (set! var1 temp1) ...
      body ...)))
```

```
(define-syntax letrec*
  (syntax-rules ()
    ((letrec* ((var1 init1) ...) body1 body2 ...) (let ((var1 <undefined>) ...) (set! var1 init1) ...
      (let () body1 body2 ...))))
```

```
(define-syntax let-values
  (syntax-rules ()
    ((let-values (binding ...) body0 body1 ...) (let-values "bind" (binding ...) () (begin body0 body1 ...))
      (let-values "bind" () tmtps body))
    (let tmtps body))
```

```
(let-values "bind" (b0 e0) binding ... tmtps body)
(let-values "mktmp" b0 e0 () (binding ... tmtps body))
```
7. Formal syntax and semantics

```
(let-values "mktmp" () e0 args
  bindings tmps body)
(call-with-values
  (lambda () e0)
  (lambda args
    (let-values "bind"
      bindings tmps body)))))

(let-values "mktmp" (a . b) e0 (arg ...)
  bindings (tmp ... ) body)
(let-values "mktmp" b e0 (arg ... x)
  bindings (tmp ... (a x)) body))

(let-values "mktmp" a e0 (arg ...)
  bindings (tmp ... ) body)
(call-with-values
  (lambda () e0)
  (lambda (arg ... . x)
    (let-values "bind"
      bindings (tmp ... (a x)) body))))

(define-syntax let*-values
  (syntax-rules ()
    ((let*-values () body0 body1 ...) (begin body0 body1 ...))
    ((let*-values (binding0 binding1 ...) body0 body1 ...)
     (let-values (binding0)
              (let*-values (binding1 ...)
                         body0 body1 ...))))

(define-syntax define-values
  (syntax-rules ()
    ((define-values () expr)
     (define dummy
      (call-with-values (lambda () expr)
                        (lambda args #f)))
    ((define-values (var) expr)
     (define var expr))
    ((define-values (var0 var1 ... varn) expr)
     (begin
      (define var0
        (call-with-values (lambda () expr)
                         list))
      (define var1
        (let ((v (cadr var0)))
         (set-cdr! var0 (cddr var0))
         v)) ...)
      (define varn
        (let ((v (cadr var0)))
         (set! var0 (car var0))
         v))))
    ((define-values (var0 var1 ... . varn) expr)
     (begin
      (define var0
        (call-with-values (lambda () expr)
                         list))
      (define var1
        (let ((v (cadr var0)))
         (set-cdr! var0 (cddr var0))
         v)) ...)
      (define varn
        (let ((v (cadr var0)))
         (set! var0 (car var0))
         v))))

(define-syntax begin
  (syntax-rules ()
    ((begin exp ...)
     (call-with-values
      (lambda () exp1)
      (lambda args exp2 ...))))

(define-syntax do
  (syntax-rules ()
    ((do ((var init step ...) ...) (test expr ...) command ...)
     (letrec
      ((loop (lambda (var ...)
              (if test
                (begin
                 (if #f #f)
                 expr ...)
                (begin
                 command
                 ...
                 (loop (do "step" var step ...))))))))
      (loop init ...))
     (do "step" x)
     x)
```

The following alternative expansion for `begin` does not make use of the ability to write more than one expression in the body of a lambda expression. In any case, note that these rules apply only if the body of the `begin` contains no definitions.

```
(define-syntax begin
  (syntax-rules ()
    ((begin exp)
     exp)
    ((begin exp1 exp2 ...)
     (call-with-values
      (lambda () exp1)
      (lambda args exp2 ...))))
```

The following definition of `do` uses a trick to expand the variable clauses. As with `letrec` above, an auxiliary macro would also work. The expression `(if #f #f)` is used to obtain an unspecific value.

```
(define-syntax do
  (syntax-rules ()
    ((do ((var init step ...) ...) (test expr ...) command ...)
     (letrec
      ((loop (lambda (var ...)
              (if test
                (begin
                 (if #f #f)
                 expr ...)
                (begin
                 command
                 ...
                 (loop (do "step" var step ...))))))))
      (loop init ...))
     (do "step" x)
     x)
```

```
Here is a possible implementation of \texttt{delay}, \texttt{force} and \texttt{lazy}. We define the expression
\begin{verbatim}
(lazy (expression))
\end{verbatim}
to have the same meaning as the procedure call
\begin{verbatim}
(make-promise #f (lambda () (expression)))
\end{verbatim}
as follows
\begin{verbatim}
(define-syntax lazy
  (syntax-rules ()
    ((lazy expression)
     (make-promise #f (lambda () expression)))))
\end{verbatim}
and we define the expression
\begin{verbatim}
(delay (expression))
\end{verbatim}
to have the same meaning as:
\begin{verbatim}
(lazy (make-promise #t (expression)))
\end{verbatim}
as follows
\begin{verbatim}
(define-syntax delay
  (syntax-rules ()
    ((delay expression)
     (lazy (make-promise #t expression)))))
\end{verbatim}
where \texttt{make-promise} is defined as follows:
\begin{verbatim}
(define make-promise
  (lambda (done? proc)
    (list (cons done? proc))))
\end{verbatim}
Finally, we define \texttt{force} to call the procedure expressions in promises iteratively using a trampoline technique following \cite{haridi} until a non-lazy result (i.e. a value created by \texttt{delay} instead of \texttt{lazy}) is returned, as follows:
\begin{verbatim}
(define (force promise)
  (if (promise-done? promise)
      (promise-value promise)
      (let ((promise* ((promise-value promise))))
        (unless (promise-done? promise)
          (promise-update! promise* promise))
        (force promise))))
\end{verbatim}
with the following promise accessor:
\begin{verbatim}
(define promise-done?
  (lambda (x) (car (car x))))
\end{verbatim}
\begin{verbatim}
(define promise-value
  (lambda (x) (cadr (car x))))
\end{verbatim}
\begin{verbatim}
(define promise-update!
  (lambda (new old)
    (set-car! (car old) (promise-done? new))
    (set-cdr! (car old) (promise-value new))
    (set-car! new (car old)))))
\end{verbatim}
The following implementation of \texttt{make-parameter} and \texttt{parameterize} is suitable for an implementation with no threads. Parameter objects are implemented here as procedures, using two arbitrary unique objects \texttt{<param-set!>} and \texttt{<param-convert>}:
\begin{verbatim}
(define (make-parameter init . o)
  (let* ((converter (if (pair? o) (car o) (lambda (x) x)))
         (value (converter init)))
    (lambda args
      (cond
       ((null? args) value)
       ((eq? (car args) <param-set!>)
        (set! value (cadr args)))
       ((eq? (car args) <param-convert>)
        converter)
       (else
        (error "bad parameter syntax")))))
\end{verbatim}
Then \texttt{parameterize} uses \texttt{dynamic-wind} to dynamically re-bind the associated value:
\begin{verbatim}
(define-syntax parameterize
  (syntax-rules ()
    ((parameterize ("step")
      ((param value p old new) ...)
      ()
      body)
    (let ((p param) ...
          (new ((p <param-convert>) value)) ...)
      (dynamic-wind
        (lambda () (p <param-set!> new) ...) ...)
        (lambda () . body)
        (lambda () (p <param-set!> old) ...))))
    ((parameterize ("step")
      args
      (param value) . rest)
      body)
    (parameterize ("step")
      ((param value p old new) . args)
      rest
      body))
    (parameterize ("step")
      (param value) ... . body)
    (parameterize ("step")
      ()
      (param value) ... . body))))
\end{verbatim}
The following implementation of \texttt{guard} depends on an auxiliary macro, here called \texttt{guard-aux}.
\begin{verbatim}
(define-syntax guard
  (syntax-rules ()
    ((guard (var clause ...) e1 e2 ...)
      (call/cc
        (lambda (guard-k)
          (with-exception-handler
            (guard-aux guard-k e1 ...))))))
\end{verbatim}
(lambda (condition)
  ((call/cc
    (lambda (handler-k)
      (guard-k
        (lambda ()
          (let ((var condition))
            (guard-aux
              (handler-k
                (lambda ()
                  (raise condition))
              clause ...))))))))
  (lambda ()
    (call-with-values
      (lambda () e1 e2 ...)
      (lambda args
        (guard-k
          (lambda ()
            (apply values args)))))))))

(define-syntax guard-aux
  (syntax-rules (else =>)
    ((guard-aux reraise (else result1 result2 ...))
     (begin result1 result2 ...))
    ((guard-aux reraise (test => result))
     (let ((temp test))
      (if temp
       (result temp)
       reraise)))
    ((guard-aux reraise (test => result) clause1 clause2 ...)...)
     (let ((temp test))
      (if temp
       (result temp)
       (guard-aux reraise clause1 clause2 ...))))
    ((guard-aux reraise (test))
     (let ((temp test))
      (if temp
       temp
       (guard-aux reraise clause1 clause2 ...))))
    ((guard-aux reraise (test result1 result2 ...))
     (if test
      (begin result1 result2 ...)
      reraise))
    ((guard-aux reraise (test result1 result2 ...) clause1 clause2 ...)...)
     (if test
      (begin result1 result2 ...)
      (guard-aux reraise clause1 clause2 ...))))

(define-syntax case-lambda
  (syntax-rules ()
    ((case-lambda (params body0 body1 ...)) ...
      (lambda args
        (let ((len (length args)))
          (let-syntax
            ((cl (syntax-rules :: ()
              ((cl}}

Appendix A. Standard Libraries

This section lists the exports provided by the standard libraries. The libraries are factored so as to separate features which might not be supported by all implementations, or which might be expensive to load.

The scheme library prefix is used for all standard libraries, and is reserved for use by future standards.

Base Library

The (scheme base) library exports many of the procedures and syntax bindings that are traditionally associated with Scheme.

Inexact Library

The (scheme inexact) library exports procedures which are typically only useful with inexact values.

```
acos asin atan
```

```
cos exp finite?
log nan? sin
sqrt tan
```
Complex Library
The (scheme complex) library exports procedures which are typically only useful with non-real numbers.

angle imag-part magnitude
make-polar make-rectangular
real-part

Division Library
The (scheme division) library exports procedures for integer division.

ceiling-quotient ceiling-remainder
centered-quotient centered-remainder
euclidean-quotient euclidean-remainder
floor-quotient floor-remainder
round-quotient round-remainder
truncate-quotient truncate-remainder
truncate-remainder truncate/

Lazy Library
The (scheme lazy) library exports procedures and syntax keywords for lazy evaluation.

delay eager force
lazy

Case-Lambda Library
The (scheme case-lambda) library exports the case-lambda syntax.

case-lambda

Eval Library
The (scheme eval) library exports procedures for evaluating Scheme data as programs.

environment eval
null-environment
scheme-report-environment

Repl Library
The (scheme repl) library exports the interaction-environment procedure.

interaction-environment

Process Context Library
The (scheme process-context) library exports procedures for accessing with the program’s calling context.

command-line exit
get-environment-variable
get-environment-variables

Load Library
The (scheme load) library exports procedures for loading Scheme expressions from files.

load

File Library
The (scheme file) library provides procedures for accessing files.

call-with-input-file
call-with-output-file
delete-file
file-exists? open-binary-input-file
open-binary-output-file open-input-file
open-output-file
with-input-from-file
with-output-to-file

Read Library
The (scheme read) library provides procedures for reading Scheme objects.

read

Write Library
The (scheme write) library provides procedures for writing Scheme objects.

display write write-simple

Char Library
The (scheme char) library provides procedures for dealing with Unicode character operations.

char-alphabetic? char-ci<=?
char-ci<=? char-ci=? char-ci>=?
char-ci>? char-downcase char-foldcase
char-lower-case? char-upper-case?
char-upcase char-numeric?
char-whitespace? digit-value
string-ci<=? string-ci<? string-ci=?
string-ci>? string-ci>=? string-downcase
string-foldcase string-upcase

Char Normalization Library
The (scheme char normalization) library provides procedures for dealing with Unicode normalization operations.

string-ni<=? string-ni<? string-ni=?
string-ni>? string-ni>=?
Time Library

The (scheme time) library provides access to time-related values.

```scheme
current-jiffy current-second
jiffies-per-second
```

Appendix B. Standard Feature Identifiers

An implementation may provide any or all of the feature identifiers listed below, as well as any others that it chooses, but must not provide a feature identifier if it does not provide the corresponding feature. These features are used by `cond-expand`.

```scheme
r7rs
  All R7RS Scheme implementations have this feature.

exact-closed
  All algebraic operations except `/` produce exact values given exact inputs.

ratios
  `/` with exact arguments produces an exact result when the divisor is nonzero.

exact-complex
  Exact complex numbers are provided.

ieee-float
  Inexact numbers are IEEE 754 floating point values.

full-unicode
  All Unicode codepoints are supported as characters (except the surrogates).

windows
  This Scheme implementation is running on Windows.

posix
  This Scheme implementation is running on a POSIX system.

unix, darwin, linux, bsd, freebsd, solaris, ...
  Operating system flags (more than one may apply).

i386, x86-64, ppc, sparc, jvm, clr, llvm, ...
  CPU architecture flags.

ilp32, lp64, ilp64, ...
  C memory model flags.

big-endian, little-endian
  Byte order flags.

⟨name⟩
  The name of this implementation.

⟨name-version⟩
  The name and version of this implementation.
NOTES

Language changes since R⁵RS

This section enumerates the differences between this report and the “Revised⁵ report” [2].

The list is incomplete and subject to change while this report is in draft status.

• Various minor ambiguities and unclarities in R⁵RS have been cleaned up.

• Libraries have been added as a new program structure to improve encapsulation and sharing of code. Some existing and new identifiers have been factored out into separate libraries. Libraries can be imported into other libraries or main programs, with controlled exposure and renaming of identifiers. The contents of a library can be made conditional on the features of the implementation on which it is to be used.

• Exceptions can now be signalled explicitly with raise, raise-continuable or error, and can be handled with with-exception-handler and the guard syntax. Any object can specify an error condition; the implementation-defined conditions signalled by error have accessor functions to retrieve the arguments passed to error.

• New disjoint types supporting access to multiple fields can be generated with SRFI 9’s define-record-type.

• Parameter objects can be created with make-parameter, and dynamically rebound with parameterize.

• Bytevectors, homogeneous vectors of integers in the range [0, 255], have been added as a new disjoint type. A subset of the procedures available for vectors is provided. Bytevectors can be converted to and from strings in accordance with the UTF-8 character encoding. Bytevectors have a datum representation and evaluate to themselves.

• The procedure read-line is provided to make line-oriented textual input simpler.

• Ports can now be designated as textual or binary ports, with new procedures for reading and writing binary data. The new predicate port-open? returns whether a port is open or closed.

• String ports have been added as a way to read and write characters to and from strings, and bytector ports to read and write bytes to and from bytevectors.

• The procedures current-input-port and current-output-port are now parameter objects, as is the newly introduced current-error-port.

• The syntax-rules construct now recognizes _ (underscore) as a wildcard, allows the ellipsis symbol to be specified explicitly instead of the default . . ., allows template escapes with an ellipsis-prefixified list, and allows tail patterns to follow an ellipsis pattern.

• The syntax-error syntax has been added as a way to signal immediate and more informative errors when a macro is expanded.

• Internal define-syntax definitions are now allowed wherever internal defines are.

• The letrec* binding construct has been added, and internal define is specified in terms of it.

• Support for capturing multiple values has been enhanced with define-values, let-values, and let*-values. Programs are now explicitly permitted to pass zero values or more than one value to continuations which discard them.

• The case conditional now supports a => syntax analogous to cond.

• To support dispatching on the number of arguments passed to a procedure, case-lambda has been added in its own library.

• The convenience conditionals when and unless have been added.

• Positive infinity, negative infinity, NaN, and negative inexact zero have been added to the numeric tower as inexact values with the written representations +inf.0, -inf.0, +nan.0, and -0.0 respectively.

• The procedures map and for-each are now required to terminate on the shortest list when inputs have different length.

• The procedures member and assoc now take an optional third argument specifying the equality predicate to be used.

• The procedures exact-integer? and exact-integer-sqrt have been added.

• The procedures make-list, list-copy, list-set!, string-map, string-for-each, string->vector, vector-copy, vector-map, vector-for-each, and vector->string have been added to round out the sequence operations.
• Implementations may provide any subset of the full Unicode repertoire that includes ASCII, but implementations must support any such subset in a way consistent with Unicode. Various character and string procedures have been extended accordingly. String comparison remains implementation-dependent, and is no longer required to be consistent with character comparison, which is based on Unicode code points. The new digit-value procedure is added to obtain the numerical value of a numeric character.

• The procedures string-ni=? and related procedures have been added to compare strings as though they had gone through an implementation-defined normalization, without exposing the normalization.

• Case insensitivity is now the default.

• There are now two additional comment syntaxes: #; to skip the next datum, and #| ... |# for nestable block comments.

• Data prefixed with datum labels #<n>= can be referenced with #<n>#, allowing for reading and writing of data with shared structure.

• Strings and symbols now allow mnemonic and numeric escape sequences, and the list of named characters has been extended.

• The procedures file-exists? and delete-file are available in the (scheme file) library.

• An interface to the system environment and command line is available in the (scheme process-context) library.

• Procedures for accessing time-related values are available in the (scheme time) library.

• A complete set of integer division operators is available in the (scheme division) library.

• The load procedure now accepts a second argument specifying the environment to load into.

• The procedures transcript-on and transcript-off have been removed.

• The semantics of read-eval-print loops are now partly prescribed, allowing the redefinition of procedures (but not syntax keywords) to be retroactive.

Incompatibilities with the main R^6RS document

This section enumerates the incompatibilities between R^7RS and the “Revised^6 report” [1].

The list is incomplete and subject to change while this report is in draft status.

• The syntax of the library system was deliberately chosen to be syntactically different from R^6RS, using define-library instead of library in order to allow easy disambiguation between R^6RS and R^7RS libraries.

• The library system does not support phase distinctions, which are unnecessary in the absence of low-level macros (see below), nor does it support versioning, which is an important feature but deserves more experimentation before being standardized.

• Putting an extra level of indirection around the library body allows room for extensibility. The R^6RS syntax provides two positional forms which must be present and must have the correct keywords, export and import, which does not allow for unambiguous extensions. The Working Group considers extensibility to be important, and so chose a syntax which provides a clear separation between the library declarations and the Scheme code which makes up the body.

• The include library declaration makes it easier to include separate files, and the include-ci variant allows legacy case-insensitive code to be incorporated.

• The cond-expand library declaration based on SRFI 0 allows for a more flexible alternative to the R^6RS .impl.sls file naming convention.

• Since the R^7RS library system is straightforward, we expect that R^6RS implementations will be able to support the define-library syntax in addition to their library syntax.

• The grouping of standardized identifiers into libraries is different from the R^6RS approach. In particular, procedures which are optional either expressly or by implication in R^5RS have been removed from the base library. Only the base library is an absolute requirement.

• Identifier syntax is not provided. This is a useful feature in some situations, but the existence of such macros means that neither programmers nor other macros can look at an identifier in an evaluated position and know it is a reference — this in a sense makes all macros slightly weaker. Individual implementations are encouraged to continue experimenting with this and other extensions before further standardization is done.

• Internal syntax definitions are allowed, but all references to syntax must follow the definition; the even/odd example given in R^6RS is not allowed.

• The R^6RS exception system was incorporated as-is, but the condition types have been left unspecified.
Specific errors that must be signalled in R⁶RS remain errors in R⁷RS, allowing implementations to provide their own extensions. There is no discussion of safety.

- Full Unicode support is not required. Instead of explicit normalization forms this report provides normalization-insensitive string comparisons that use an implementation-defined normalization form (which may be the identity transformation). Character comparisons are defined by Unicode, but string comparisons are implementation-dependent, and therefore need not be the lexicographic mapping of the corresponding character comparisons (an incompatibility with R³RS). Non-Unicode characters are permitted.

- The full numeric tower is optional as in R⁵RS, but optional support for IEEE infinities, NaN, and -0.0 was adopted from R⁶RS. Most clarifications on numeric results were also adopted, but the R⁶RS procedures real-valued?, rational-valued?, and integer-valued? were not. The R⁶RS names inexact->exact for exact and exact->inexact for inexact were retained, with a note indicating that their names are historical. The R⁶RS division operators div, mod, div-and-mod, div0, mod0 and div0-and-mod0 have been replaced with a full set of 18 operators describing 6 different rounding semantics.

- When a result is unspecified, it is still required to be a single value, in the interests of R⁵RS compatibility. However, non-final expressions in a body may return any number of values.

- Because of widespread SRFI 1 support and extensive code that uses it, the semantics of map and for-each have been changed to use the SRFI 1 early termination behavior. Likewise assoc and member take an optional equal? argument as in SRFI 1, instead of the separate assp and memp procedures of R⁵RS.

- The R⁶RS quasiquote clarifications have been adopted, but the Working Group has not seen convincing enough examples of multiple-argument unquote and unquote-splicing, so they are not provided.

- The R⁶RS method of specifying mantissa widths was not adopted.

Incompatibilities with the R⁶RS Standard Libraries document

This section enumerates the incompatibilities between R³RS and the R⁶RS [1] Standard Libraries.

The list is incomplete and subject to change while this report is in draft status.

- The low-level macro system and syntax-case were not adopted. There are two general families of macro systems in widespread use — the syntax-case family and the syntactic-closures family — and they have neither been shown to be equivalent nor capable of implementing each other. Given this situation, low-level macros have been left to the large language.

- The new I/O system from R⁶RS was not adopted. Historically, standardization reflects technologies that have undergone a period of adoption, experimentation, and usage before incorporation into a standard. The Working Group was unhappy with the redundant provision of both the new system and the R⁵RS-compatible “simple I/O” system, which relegated R⁵RS code to being a second-class citizen. However, binary I/O was added using binary ports that are at least potentially disjoint from textual ports and use their own parallel set of procedures.

- String ports are compatible with SRFI 6 rather than R⁶RS; analogous bytevector ports are also provided.

- The Working Group felt that the R⁶RS records system was overly complex, and the two layers poorly integrated. The Working Group spent a lot of time debating this, but in the end decided to simply use a generative version of SRFI 9, which has near-universal support among implementations. The Working Group hopes to provide a more powerful records system in the large language.

- Enumerations are not included in the small language.

- R⁶RS-style bytevectors are included, but provide only the “u8” procedures in the small language. The lexical syntax uses #u8 for compatibility with SRFI 4, rather than the R⁵RS #\u8 style. With a library system, it’s easier to change names than reader syntax.

- The utility macros when and unless are provided, but since it would be meaningless to try to use their result, it is left unspecified.

- The Working Group could not agree on a single design for hash tables and left them for the large language.

- Sorting, bitwise arithmetic, and enumerations were not considered to be sufficiently useful to include in the small language. They will probably be included in the large language.

- Pair and string mutation are too well-established to be relegated to separate libraries.

ADDITIONAL MATERIAL

The Internet Scheme Repository at...
The Scheme community website at http://schemers.org/ contains additional resources for learning and programming, job and event postings, and Scheme user group information.

A bibliography of Scheme-related research at http://library.readscheme.org/ links to technical papers and theses related to the Scheme language, including both classic papers and recent research.

EXAMPLE

The procedure integrate-system integrates the system

\[ y'_k = f_k(y_1, y_2, \ldots, y_n), \quad k = 1, \ldots, n \]

of differential equations with the method of Runge-Kutta.

The parameter system-derivative is a function that takes a system state (a vector of values for the state variables \( y_1, \ldots, y_n \)) and produces a system derivative (the values \( y'_1, \ldots, y'_n \)). The parameter initial-state provides an initial system state, and \( h \) is an initial guess for the length of the integration step.

The value returned by integrate-system is an infinite stream of system states.

```scheme
(define integrate-system
  (lambda (system-derivative initial-state h)
    (let ((next (runge-kutta-4 system-derivative h)))
      (letrec ((states
                    (cons initial-state
                          (delay (map-streams next states))))))
        states))))
```

The procedure runge-kutta-4 takes a function, \( f \), that produces a system derivative from a system state. It produces a function that takes a system state and produces a new system state.

```scheme
(define runge-kutta-4
  (lambda (f h)
    (let ((*h (scale-vector h))
           (*2 (scale-vector 2))
           (*1/2 (scale-vector (/ 1 2)))
           (*1/6 (scale-vector (/ 1 6))))
      (lambda (y)
        ;; y is a system state
        (let* ((k0 (*h (f y)))
               (k1 (*h (f (add-vectors y (*1/2 k0)))))
               (k2 (*h (f (add-vectors y (*1/2 k1)))))
               (k3 (*h (f (add-vectors y k2)))))
          (add-vectors y
                       (*1/6 (add-vectors k0
                                (*2 k1)
                                (*2 k2)
                                k3))))))))
```

```scheme
(define elementwise
  (lambda (f)
    (lambda vectors
      (generate-vector (vector-length (car vectors))
                       (lambda (i)
                        (apply f
                                (map (lambda (v) (vector-ref v i))
                                     vectors)))))))
```

```scheme
(define generate-vector
  (lambda (size proc)
    (lambda vectors
      (elementwise proc vectors
                    (vector-length vectors)
                    (lambda (i)
                        (apply proc
                                (map (lambda (v) (vector-ref v i))
                                     vectors)))))))
```
(let ((ans (make-vector size)))
  (letrec ((loop
         (lambda (i)
             (cond ((= i size) ans)
                   (else
                        (vector-set! ans i (proc i))
                        (loop (+ i 1)))))
          (loop 0))))

(define add-vectors (elementwise +))

(define scale-vector
  (lambda (s)
      (elementwise (lambda (x) (* x s))))))

The map-streams procedure is analogous to map: it applies its first argument (a procedure) to all the elements of its second argument (a stream).

(define map-streams
  (lambda (f s)
      (cons (f (head s))
            (delay (map-streams f (tail s))))))

Infinite streams are implemented as pairs whose car holds the first element of the stream and whose cdr holds a promise to deliver the rest of the stream.

(define head car)
(define tail
  (lambda (stream) (force (cdr stream))))

The following illustrates the use of integrate-system in integrating the system

\[
C \frac{dv_C}{dt} = -i_L - \frac{vc}{R}
\]

\[
L \frac{di_L}{dt} = vc
\]

which models a damped oscillator.

(define damped-oscillator
  (lambda (R L C)
     (lambda (state)
         (let ((Vc (vector-ref state 0))
               (Il (vector-ref state 1))
               (vector (- 0 (+ (/ Vc (* R C)) (/ Il C))
                         (/ Vc L)))))))

(define the-states
  (integrate-system
    (damped-oscillator 10000 1000 .001)
    '#(1 0)
    .01))
